A LEADING article which appeared in THE LANCET of Jan. 26th, taking as the text for comment an address by Dr. Emil Amberg upon the need of reciprocity in medical practice between the various States of the American Union, aroused much interest in this country. Of course, it would be but a trite remark to make that the leaders of the medical profession in the United States and a majority of the practitioners recognise clearly and confess freely that things are not as they should be with regard to medical education and laws here, and that efficient reforms might and ought to be introduced as quickly as possible. The difficulty has ever been how and where to begin. It would seem now as if an energetic and definite attempt is to be made to grapple with the problem. A committee of the American Medical Association on Organisation has recently published its report in the Journal of the Association and in other medical journals, part of which, dealing with the question of medical education reads as follows:—"As is well known the subject of medical education was taken up by the association early in its existence, and much was done to raise the standard, but in recent years little has been attempted. At the present time there are altogether too many medical colleges, and one of the greatest dangers which now threatens the medical profession in this country is found in just this fact. This is not due alone to the pouring into the profession each year thousands of illy-prepared men, with a lesser proportion it may be of those who are really fitted for their life-work, but in the commercialism, the strife, the petty ambitions and general demoralisation which go with these, including free dispensaries, free clinics, and free hospital service. The evils are brought on by ourselves and can be corrected only by our own efforts. There is to-day, however, no way for the profession of this country to act upon this question in an organised capacity. .. .... The question is one that cannot be settled by legislation nor by public sentiment, but by professional sentiment, and when this can be created in the right way and a solution of the question proposed, professional sentiment will carry out the plan adopted." With respect to medical legislation and reciprocity the same report says: "We have here a peculiar position. There are 50 different territorial subdivisions, if the district of Columbia and the territories are considered with the States, and no two of them have the same medical laws. Yet there is not a medical law on the statute books of any of the States or territories that was not put there through the efforts of physicians. ...... It is presumed that if a few States had a law that was giving satisfaction, it would not be much trouble to get that law passed in those States which had not adopted it. It may also be presumed that if the profession asked for the same enactment in every State and persisted in its demands, it would in time get such a law. The profession would be working for a common purpose in every State in the country, and before long the essential features of the ideal law that was agreed upon would be adopted. At present, however, there seems to be no way by which the various State societies can get together to consider such a matter. The need of reciprocity comes from the fact that in enacting medical laws in one State no regard has been had for what might be done in this direction in another." Each State is indeed a law unto itself and only takes such action in medical legislation as its medical advisers represented by the State societies deem will best suit its own interests, and ignores the fact that the brethren in neighbouring States may be injuriously affected by such legislation. However, all this is well known in every part of the United States, and a large number of medical men in Great Britain are almost as conversant with the true condition of affairs. It is hoped that by careful organisation of the medical profession throughout America this anomalous and, to a great extent, disastrous situation may be changed and reforms introduced which will place the question of inter-State reciprocity on a sound and workable basis. In the report the members of the committee explain at length the steps which in their opinion should be taken to bring about so desirable a consummation, and they conclude by expressing the belief that their recommendations are in no way Utopian or impracticable, but that they are such as can be carried out in every part of their great country and that they will result in a scientific, social, and material benefit to the individual and to the profession as a whole, as well as to the well-being of the people. There can be no doubt that necessary reforms will not be put through at once or without much difficulty, but a beginning must be made and it is a healthy sign that the association intend to push forward.

The Cost of Crime in the United States.

Mr. Eugene Smith of New York has recently published in pamphlet form a paper on this subject which he read before the National Prison Association at its annual meeting of 1900 held at Cleveland, Ohio, and which contains much interesting information. In analysing the statistics of certain large cities in the United States where the statistics are known to be accurate and complete, the following figures are given as the cost of crime in New York, Cleveland, Chicago, St. Louis, San Francisco, Richmond, Charlestown, Savannah, and New Orleans. The cost of crime in the city of New York paid from city and county taxation reaches the portentous total of $20,000,000 (£4,000,000), giving an average charge of over $6 (£1 4*s.*) for each individual in its population. In San Francisco the average charge per person is about $5 (£1), and in the other cities named the per capita tax runs with slight variation, from $3 (12*s.*) to $3·50 (14*s.*). The striking excess of the rate in New York and San Francisco above that of the other cities is explained in part by one very important fact—in New York and San Francisco the rate includes county taxation while the rate in other cities does not. From such light, says Mr. Smith, as can be gained from the reports of these cities and from other sources it would appear that about $1 (4*s.*) should be added to the prevailing per capita rate of from $3 (12*s.*) to $3 50 (14*s*) in order to include county taxation. This makes the total amount of both city and county taxation caused by crime paid by the dwellers in cities average from $4 (16*s.*) to $4·50 (18*s.*) for each inhabitant; but to cover variations and to make the final result a conservative one I should prefer to reduce the estimate as low as $3 50 (14*s.*) per capita. Mr. Smith estimates that there are at least 250,000 criminals in the United States and that each one earns yearly on an average *$1600 (£320)*, representing an annual aggregate income of $400,000,000 (£80,000,000). To this must be added the yearly taxation caused by crime of $200,000,000 (£40,000,000), giving the enormous total of $600,000,000 (£120,000,000). These figures are startling in their magnitude and even if they are exaggerated somewhat they convey a fairly accurate notion of the cost of crime from a pecuniary standpoint.

Obituary.

THOMAS BOND, F.R.C S. ENG., M B , B.S. LOND.

MR. THOMAS BOND, whose death under very sad circumstances we announced in THE LANCET of June 8th, p. 1618, was a man of many parts. Coming of a Somersetshire family he not only had numerous county friends, acquaintances, and experiences, but in his career as surgeon in the Prussian service, to a large London hospital, to the police, and to sundry railway companies, as well as being a well-known figure in the hunting field, he accumulated experiences among all classes, and there was, perhaps, no medical man who could recall more remarkable incidents of practice. He commenced his medical studies by being a pupil of his uncle, Dr. McCann of Southampton. Coming to London he entered at King's College Hospital and gained the Gold Medal at the B.S. examination of the University of London. His first appointment was that of house surgeon to Sir William Fergusson of whom he could tell many stories. Once when the carotid was cut and spouted freely Fergusson did not stir, but said to Bond, "Put your finger on it, mon." Whilst he (Fergusson) was excising the knee he cut the popliteal artery and forthwith amputated. Then turning to the gallery he said, "You notice, gentlemen, that in the middle of the operation I changed my mind." After having dined at Greenwich Bond was made to walk all the way home with him.

In 1866, having finished at the hospital, Mr. Bond joined the Prussian military service where he had full experience of a cholera epidemic He was himself saved by a heroic dose of castor oil taken at the onset. He further ventured his neck in carrying a despatch from the Prussian, through the Austrian, into the Italian lines. Returning home he set up practice in Westminster, succeeding to that of "old Dr. McCann" of Parliament street, and lived for a time in Delahay-street before going to Broad Sanctuary. His first experience of railway accidents consisted in his train being overturned into shallow water, when he gave immediate aid to the injured. His last important work was in connexion with the Slough accident, which obliged him whilst suffering to travel as far as Balmoral one way and Penzance the other.

Having set his mind on being one of the staff at the Westminster Hospital, he had to face several contested elections before winning the post, which he did in 1873 Even then he spent practically all his life there as assistant surgeon, so that he had no opportunity of following up the promise he gave as a student of becoming a prominent operating surgeon. It was only some five years ago that he was appointed full surgeon. The surgery he chiefly had to do was, to use his own words, "of the fore and aft sort." When he at last did become full surgeon it was too late for him to begin many modern operations. Besides, his accommodation was defective and he had scarcely as much "nerve" in the operating theatre as when riding at a fence. He had, indeed, evidently been much impressed by the large mortality which attended the surgery of former days, and this impression weighed heavily against himself when illness came.

One day he was called into the Law Courts at Westminster where a judge had been seized with apoplexy, a case which started his large legal connexion and at the same time introduced him to the judge's daughter whom he married. It is mournful to think that she also had a lingering and painful illness before her death some two years ago. His house being near the headquarters of the police and his service as surgeon to the A Division, to which he was appointed in 1867, led to his connexion with many important criminal causes. Among these were the case of Kate Webster, the Lamson case, the Pearcey case, the Whitechapel murders, and the Lefroy case. By common consent he was the best of medical witnesses. His clear evidence inspired the bench and the bar with the fullest confidence, and he was never afraid to say "I don't know." His reminiscences put novels of the "detective" order into the shade. His extraordinary experience of railway accidents rendered him proof against malingering of whatever kind, although he had sometimes to expose frauds which had imposed upon less experienced men. It would have been better perhaps for him if he had confined himself to strictly medical duties and not yielded sometimes to pressure put upon him by the railway companies to act as a go-between in fixing the amount of compensation for accidents.

As regards non professional occupations Mr. Bond was brought up to horses from a boy, and he rode well and hard with a good seat and at a pace which did not spare his horse He hunted regularly, of late years chiefly with the Badminton hounds from Chippenham. But what he looked forward to most of all was the staghunt on Exmoor in August and September, riding out to the meets from his house at Dunster. He knew his way among the bogs as a native, he could get down and up again out of a combe quicker than most, and none knew better where to wait for the stag to break up from the woods by the sea near Glenthorne. Perhaps of all his accomplishments he himself set most store on his knowledge of horseflesh, as controversial a matter as the medico-legal subjects in which so much of his practice lay. He often acted as judge at the more important horse shows. His multifarious duties strained the health of a really strong man. He would return to Paddington by night and sleep on in the carriage until morning, then do a full day's work, and after that sit up late over legal and police reports. Riding tended of late to irritate a slight organic contraction and the spasm set up led to instrumentation often under unfavourable circumstances, so that a lesion attended by thickening was started at and below the neck of the bladder, whilst the organs above remained healthy throughout. Hence a terrible vicious circle, the necessity for instrumentation, and the spasm and radiating pains which this caused.

In addition, latterly there were attacks of general rheumatic pains with rigors and sweating. Insomnia in middle life from overwork had tempted him towards the use of narcotics. Even then he used to say that the impulse which afterwards caused his death forced itself into his mind and it constantly recurred when he was driven wild by pain during his last illness. He retained, except when suffering, those characteristics which will recall him to that vast number of acquaintances who have heard of his sad death with grief. He was buried on June 10th in the little country churchyard of his old home at Orchard Portman.

JAMES AITKEN MYRTLE, M.D. Edin.

As we announced in our issue of June 8th Dr. James Aitken Myrtle died very suddenly on June 1st. Dr. Myrtle, who was in his 41st year, was born in Harrogate and educated at Winchester College and Edinburgh University, where he graduated as M.B. and C.M. in 1882. He then proceeded to Vienna and Würzburg to study diseases of the skin and other special branches of medicine and after about one year's absence he returned home and joined his father, Dr. A. S. Myrtle, in practice at Harrogate. In 1885 he graduated as M.D. He was co-editor with his father of a book entitled "Practical Observations on Harrogate Mineral Waters" and he also contributed papers upon "Paroxysmal Hæmaturia" and "Gout, Rheumatism, and Rheumatoid Arthritis" to the medical journals. Dr. Myrtle was well known as a politician. In the field of medical politics he was an ardent advocate of medical defence—a subject which he brought forward at many meetings of the British Medical Association, notably at Edinburgh in 1898. But if in professional politics he was a reformer, in those of the State he was a strong Conservative. He had been a member of the town council for five years, and at the time of his death was serving as mayor for the second time. A keen sportsman and in his younger days a good all-round athlete, his greatest pleasure was hunting and he was a bold and skilful horseman. He was surgeon-lieutenant to the Yorkshire Yeomanry Hussars and had always taken a keen interest in volunteering, having been a member of the cadet corps at Winchester. In 1887 he married, but he had no children. The funeral took place on June 5th, the procession from the church to the cemetery including officers and men of the Yorkshire Yeomanry Hussars, the local members of the 1st Volunteer Battalion West Yorkshire Regiment, and the civic dignitaries and members of public bodies.

Notification Prosecutions.—At the Exeter Police-court on June 7th five persons were fined in sums ranging from £1 10*s*. to half a crown for failing to notify cases of scarlet fever and permitting children suffering from it to be at large. The town clerk stated that the medical officer of health had visited the schools and found about a dozen children in the desquamating stage of scarlet fever. These cases had produced an epidemic of the disease and through the neglect of the parents had cost the city from £300 to £400.

The State Children's Association.—In the fourth annual report of the State Children's Association reference is made to a speech by Mr. Chaplin in which, while congratulating the barrack school officials on the improvements recently effected in the schools, he said that the policy of the future would be that of rearing children by methods of segregation—which are the methods the association exists to promote—and to a quotation from a circular issued by the Local Government Board to every board of guardians suggesting "that by the provision of cottage homes, by the hire of scattered homes, by boarding-out and emigration, children might be entirely removed from the workhouse and its associations. There are still 3141 children in the metropolitan infirmaries and workhouses—a larger number than in 1894—notwithstanding the official condemnation of the practice of keeping children in such unsuitable environment, and although barrack schools have been condemned the expenditure of £48,000 has within the last five years been sanctioned by the Local Government Board on their structural improvement. The report, which is an instructive document dealing with social reform, can be obtained at the offices of the association, 58, Old Broad-street, E.C., and from Messrs P. S. King and Son, 2 and 4, Great Smith-street, Westminster.

THE GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION.

◆

Thursday, June 6th.

The Council met to-day with Sir William Turner, the President, in the chair, and resumed the work of its session.

Recognised Scientific Institutions.

The Executive Committee presented a report in which there was submitted for the approval of the Council a list of scientific institutions other than universities or schools of medicine recognised by licensing bodies as places where the course of medical study may be commenced by applicants for registration in the Medical Students' Register.

Several members took exception to the list and it was arranged that it should go back to the Executive Committee for amendment.

The Case of Walter Randall Knightley, R.N.

The Council then took up the consideration of the case of Walter Randall Knightley, R.N., registered as Mem. R. Coll. Surg. Eng., 1892; Lic. R. Coll. Phys. Lond., 1892, who had been summoned to appear before the Council in consequence of a judgment given in the High Court of Justice, Probate, Divorce, and Admiralty Division on Dec. 21st, 1900, in the case of Harvest *v.* Harvest and Knightley.

Mr. Knightley attended with Mr. Cripps, K.C., M.P., and Mr. Heaton, solicitor, as his legal representatives.

The President explained that the case would be conducted by the solicitor to the Council.

Mr. Winterbotham said that the case was one in which there was no complainant. His attention had been called to it by what had appeared in the public press and he thought it was a case which should be brought to the notice of the Council in order that it might consider whether Mr. Knightley's conduct was such as came within the definition of "infamous conduct in a professional respect." The facts in the case were that Mr. Knightley was a surgeon in the Navy and was on duty at Gosport when called in to attend professionally the wife of Major Harvest and the jury found that Mr. Knightley committed adultery with Mrs. Harvest and gave the petitioner £4000 damages. Mr. Winterbotham read to the Council the charge to the jury delivered by Sir Francis Jeune, President of the Court, in which Mr. Knightley's conduct was severely condemned.

Mr. Cripps, in addressing the Council, said that the main point he wished to press was the question whether anything could be shown in mitigation. He was not instructed by the solicitors who had conducted Mr. Knightley's case in the divorce proceedings and what he wished to urge was that the Council should postpone consideration of the case. He asked this because if his client were struck off the Register that *ipso facto* would deprive him of his position in the Royal Navy as a medical officer. His client had begun his connexion with the Royal Navy in 1893. He had served on H.M.S. *Excellent*, on H.M.S. *Albacore*, on H.M.S. *Camperdown*, and as surgeon to the Royal Marines. After the divorce case all the documents in the case had been placed before the naval authorities, and subsequently to examination of them Mr. Knightley had been appointed as surgeon to H.M.S. *Harrier*, a position which he at present occupied. The certificates he had received from the captains he had served under showed that he was a man of sobriety and good conduct. Having now been in the navy for nearly eight years Mr. Knightley required to serve only eight months more to earn a gratuity of £1000 on retirement. He, however, wished to remain a naval officer. He did not wish to retire from the service, nor did he intend, should he retire from the navy, to follow the practice of an ordinary medical practitioner.

Mr. Knightley was asked to go into the witness-box. He went there and bore out the statements of Mr. Cripps as to his naval career and mentioned that his family, as a compromise, had paid £3000 in respect to the damages awarded by the jury in the divorce case.

No questions were asked by the Council. After deliberating on the case *in camerâ*

The President announced the Council's decision. Addressing Mr. Knightley he said: I have now to tell you that the Council has judged you to have been guilty of "infamous conduct in a professional respect" and has directed its registrar to erase your name from the Medical Register.

Dental Cases.

The REGISTRAR (Mr. ALLEN) read a report by the Dental Committee on the case of Mr. George Thomas Ockleford Crocker, which was as follows:—

The complaint against George Thomas Ockleford Crocker having been referred to the Dental Committee to ascertain the facts the
[illegible] follows On Feb 26th, 1901, the
[illegible] attended before the committee
[illegible] James Lorden Crocker (by Mr
[illegible] inant; and Mr George Thomas
[illegible], his counsel, instructed by Mr.
[illegible]

[illegible] uthampton. (b) In the month
[illegible] complained of occurred, Mr.
[illegible]
dated June 19th and Nov. 4th, 1900.

Mr. Percy James Nicholls appeared with Mr. Crocker as his solicitor.

It was decided to hear parties rather than to proceed forthwith on the report from the Dental Committee.

Mr. NICHOLLS said that in these circumstances he did not know what the procedure could be, as the complainant, Mr. Crocker's brother, was not present.

Mr. TOMLS, Mr. HORSLEY, Sir WILLIAM THOMSON, Dr. GLOVER, and Dr. McVAIL wished for further information, and Mr. CROCKER went into the witness-box and answered several questions put to him by those members. Thereafter the case was considered *in camerâ*. On the readmission of the public

The PRESIDENT, addressing Mr. CROCKER, said: The Council has deliberated on your case and the Council acquits you.

The REGISTRAR read a report by the Dental Committee on the case of Mr. Alexander Wood Donaldson, dentist, Bury St. Edmunds, Suffolk. This report was as follows:—

The complaint against Alexander Wood Donaldson having been
[illegible] ain the facts, the Dental
[illegible] Feb. 26th, 1901, the said
[illegible] ersonally, but Mr. Arthur

[illegible] eclaration read by his
solicitor) apologised for what he had done, stating that he erred
[illegible]
[illegible] . Donaldson to the solicitor to the
[illegible] Jan. 30th, 1901, with copy advertisement inclosed; and an affidavit of Mr. Donaldson, dated Feb. 26th, 1901.

Mr. TOOVEY appeared to represent the accused and presented a medical certificate showing that Mr. Donaldson was not in the a fit condition of health to travel to London

After consideration of the circumstances the Council resolved that further consideration of the charge should be postponed until the November session, the PRESIDENT informing Mr. Toovey that the Council would expect Mr. Donaldson to appear then.

In the course of some conversation on the case it was suggested that "R.D S." meant "Registered Dental Surgeon."

The Council and the English Royal Colleges.

The Council proceeded to the consideration of communications from the Royal College of Physicians of London and the Royal College of Surgeons of England declaring that these Colleges could no longer require the registration of students by the General Medical Council as a condition of admission to examination for their diplomas.

The PRESIDENT pointed out that the letter from the Royal College of Physicians was a communication forwarded on behalf of the President and Fellows of the College, whereas that from the Royal College of Surgeons was sent on behalf of the College.

Mr. BRYANT, in answer to Mr. HORSLEY'S inquiry as to whether the communication from the Royal College of Surgeons had been presented to the Fellows of the College, stated that the letter came from the Council who are the executive body which governs the College of Surgeons.

Dr. McVAIL said that the new regulations of these Colleges seemed doubtful in respect to the length of the medical curriculum He wanted to have it made quite clear if there was to be a five years' medical course subsequent to the passing of the preliminary examination in arts.

Dr. NORMAN MOORE: The medical study of a student must be study after he has passed his preliminary examination.

Dr. McVAIL: Do the Royal Colleges recognise chemistry, physics, and biology as medical studies?

Dr. NORMAN MOORE These subjects are included in the curriculum and are part of what is meant as medical study.

Dr. McVAIL was not sure that the Colleges took that view, because they permitted the subjects in question to be taken before the passing of the preliminary examination and thus practically reduced the medical course of study from five to four years.

Dr. NORMAN MOORE said that the Royal College of Physicians had never intended so to reduce the curriculum.

Dr. McVAIL hoped that it was so, and he would be delighted to have it made perfectly clear that the Colleges contemplated not a four years' medical course after the preliminary examination but in reality a six years' course where chemistry, physics, and biology were taken before the preliminary examination. He thought an investigation of the actual terms of the new regulations was very necessary.

Sir CHRISTOPHER NIXON thought the statement of Dr. Norman Moore had cleared up a great deal that was doubtful in this matter. From the statement it was quite clear that the Royal Colleges intended to retain the *five years* after the preliminary examination. In these circumstances, what did the whole dispute between the Council and the Colleges amount to? Simply this, that the Colleges recognised a larger number of scientific institutions than was recognised by the Council. That surely was a small matter to produce so much cleavage, and if it really was the question in dispute it surely could *be settled by some amicable arrangement.* It would be disastrous if there was to be a continuance of difference over such a matter. What he thought the Council would have to do was to find out what scientific institutions had the proper means of teaching the required subjects and recognise such institutions when found.

It was agreed to postpone further discussion till the next *day and the Council adjourned.*

FRIDAY, JUNE 7TH.

The Council resumed work to-day with Sir WILLIAM TURNER, the President, in the chair.

The President and the British Association.

The PRESIDENT said that with the consent of the Council he would leave the chair for about an hour in order to preside at a meeting of the Council of the British Association, and in accordance with custom he would ask the senior treasurer, Mr Bryant, to take his place during his absence.

The proposal met with the approbation of the Council.

The Council and the English Royal Colleges.

The first business on the programme was the consideration of the communications from the English Royal Colleges with regard to the resolution adopted by the Council on Dec. 4th, 1900, viz:—

That the Royal Colleges be informed that the Council, having taken into consideration the memoranda of the Colleges and the legal opinions relating thereto has resolved to continue to adhere to its resolution with regard to the registration of medical students.

The communications as set out in the programme were as follows, viz. :—

(a) From the Royal College of Physicians.

London, S.W., May 14th, 1901.

Sir,—I am requested by the President and Fellows of this College to acquaint you, for the information of the General Medical Council, that in consequence of the adherence of the Council to their Regulation of June 7th, 1899, in reference to the registration of students, as announced in their resolution of Dec. 4th last, this College can no longer require the registration of students by the General Medical Council as a condition of admission to examination for its diplomas; and that, in accordance with the same decision on the part of the Royal College of Surgeons of England, the regulations for the qualifications of the two Colleges have been altered as in the inclosed copy.

I am, Sir, your obedient servant,
Edwd. Liveing, Registrar.

To the Registrar of the General Medical Council.

(b) From the Royal College of Surgeons of England.

Royal College of Surgeons of England, Lincoln's-inn-fields,
London, W.C., May 13th, 1901.

Sir,—I am directed to inform you that, in consequence of the adherence of the General Medical Council to their Regulation of June 7th, 1899, in reference to the registration of students, as announced in their resolution of Dec 4th last, this College can no longer require the registration of students by the General Medical Council as a condition of admission to examination for its diplomas, and that in accordance with this decision and with the same decision on the part of the Royal College of Physicians of London the regulations for the qualifications of the two Colleges have been altered as in the inclosed copy.

I am, Sir, your obedient servant,
S. Forrest Cowell, Secretary.

The Registrar, General Medical Council.

(c) Regulations Appended.

SECTION I.

Professional Education.

I. Any candidate who desires to obtain the Licence of the Royal College of Physicians of London and the Diploma of Member of the Royal College of Surgeons of England is required to complete* five years of professional study after passing a recognised preliminary examination on the subjects of general education, to comply with the following regulations, and to pass the examinations hereinafter set forth. (See Section II.)

II. Every such candidate who shall commence professional study on or after the 1st of January, 1892, will be required to produce the following certificates before admission to the several examinations:—

First Examination.

1. Of having passed one of the preliminary examinations in general education recognised by the Examining Board in England, a list of which may be obtained on application.
2. Of having received instruction in the following subjects:—
   † (a) Chemistry and physics, and practical chemistry.
   ‡ (b) Practical pharmacy.
   † (c) Elementary biology.

SECTION II.

VI. A candidate will be admitted to examination in chemistry and physics and elementary biology on producing evidence of having complied with the regulations prescribed in Section I., Paragraph II., Clause 2 (a) and (c); and to examination in practical pharmacy on producing evidence of having complied with the regulations prescribed in Section I., Paragraph II., Clause 2 (b), *or he may take pharmacy at any time during the curriculum.*

XII. Candidates will be admissible to the second examination on the completion of two winter sessions and one summer session (or 15 months during the ordinary sessions) at a recognised medical school and after the lapse of not less than one year (one winter and one summer session) from the date of passing Parts I. and III. of the first examination, and on producing evidence of having complied with the regulations prescribed in Section I., Paragraph II., Clauses 3 and 4.

XVII. Candidates who have passed the second examination will be admissible to the third or final examination on production of the required certificates of study at the expiration of five years (five winter and five summer sessions) from the date of passing the preliminary examination and at the expiration of four years (four winter and four summer sessions) from the date of passing Parts I. and III. of the first examinations and of two years (two winter and two summer sessions) from the date of passing the second examination.

---

* The first of the five years may be spent at an institution, other than a medical school recognised by the Board, for instruction in chemistry, physics, practical chemistry, and biology, or six months may be spent in attendance at a similar institution in receiving instruction in chemistry, physics, and practical chemistry only. Four complete years of professional study must be attended at a recognised medical school and hospital after passing Parts I. and III. of the first professional examination.

† These subjects may be studied at institutions recognised for the purpose by the Examining Board in England, a list of which may be obtained on application.

‡ The instruction in practical pharmacy must be given by a registered medical practitioner, or by a member of the Pharmaceutical Society of Great Britain, or in a public hospital, infirmary, or dispensary.

Dr. McVail asked for information about Part II.

Dr. Norman Moore said that Part I. was chemistry, physics, and practical chemistry, Part II. pharmacy, and Part III. biology.

Dr. McVail then pointed out that the regulations were not complete.

Dr. Norman Moore said that the only regulations sent to the Council on this occasion were those in which alterations had been made, but of course the Council already possessed the regulations in their entirety.

Mr. Horsley thought the document in its present form was incomprehensible.

Dr. MacAlister said that what appeared on the programme was precisely what had been sent to the Council by the Royal Colleges.

Dr. Heron Watson submitted that the Council should not be asked to discuss this important matter until they had the whole state of the case before them.

Dr. Norman Moore assured the Council that the Royal Colleges would be delighted to supply members with the complete regulations.

Dr. MacAlister, seconded by Mr. Young, moved that the communications be received and entered in the minutes and that notes be added explanatory of the references.

Dr. McVail thought there should be a postponement.

Dr. Heron Watson said that he wanted to pin the Royal Colleges down to what their regulations were.

The motion was put from the chair and accepted without a vote.

Dr. McVail then moved that the consideration of the subject be adjourned until the members of the Council had obtained copies of the complete regulations.

Dr. Norman Moore said that the Royal Colleges could not supply copies of the obsolete regulations, but they could and would supply copies of the regulations now in force. He objected to Dr. Heron Watson speaking about pinning the Royal Colleges down. All that had been done had been done openly, and he did not think it was an expression which should be used about any qualifying body.

Dr. Glover protested against this waste of time.

Dr. Heron Watson seconded the motion for the adjournment.

On the vote being taken 12 members voted for the motion, 10 against it, and 9 abstained from voting.

The consideration of the communications was accordingly adjourned.

Annual Report of the Finance Committee.

The Council then dealt with the report by the Finance Committee on the income and expenditure for 1900. The report stated that the income of the General and Branch Councils for the year ending Dec. 31st, 1900, was £8657 8s. 7d. and the expenditure for the same period £9694 19s. 8d. Consequently there was a deficit on the year's working of £1037 11s. 1d. The receipts from fees were practically the same as in 1899, England having received £140 15s. less, Scotland £77 13s. more, and Ireland £73 17s. 6d. more, the net total increase being £10 15s. 6d. The actual law expenses in 1899 were £612 2s. 6d. and in 1900 they were £557 1s. 5d., a decrease of £55 1s. 1d. During the last seven years, the Pharmacopœia being excluded, the expenditure had exceeded the income on an average by £1044 1s. 1d. The total sum expended on the alteration of the Council's buildings had been £3263 19s. 6d. The expenditure on the acquisition of the property and its subsequent alterations amounted to £25,770 19s. 6d., against which the English Branch Council held a mortgage of £25,500 at 3 per cent., leaving an unsecured debt of £270 19s. 6d., which it was proposed to secure by a further endorsement on the mortgage deed. With regard to the Irish Branch Council, its receipts from fees were £886 and its expenditure was £1199 18s. 8d., leaving a deficit on the year's working of £313 11s. 2d. The Council made a grant of £500 to its funds, and a balance was brought forward from 1899 of £62 6s. 2d., so that the cash in hand at the end of the year amounted to £248 15s. Supposing that the income for 1901 was the same as that for 1900—viz., £886—by adding it to the balance in hand they got a total of £1132. The expenditure for 1900 was £1200, and the committee, in view of the fact that the expenditure would probably be rather higher this year on account of the cost of the election of a Direct Representative, recommended that a further grant of £500 be made to the Irish branch. As to dental finance, the receipts were £992 4s. 5d. and the expenditure amounted to £735 14s., leaving a surplus of £256 9s. 7d. on the year's working.

Mr. Bryant, chairman of the committee, moved that the report be received, entered on the minutes, and adopted. He pointed out that the expenditure included such items as the grant of £500 to the Irish Branch Fund, which was received back, and the contribution of £215 to the Sinking Fund, a fund which was a gradually increasing asset of the Council. The receipts and expenditure in connexion with the

Pharmacopœia were now kept in a separate account. This account showed a deficit on the year of £288 8*s.* 7*d.*, but he was told that there was at present about £290 in the hands of the printer, so that there was really no deficit.

Dr. **PETTIGREW** seconded the motion.

The motion was adopted by the Council.

The Finances of the Council.

Mr. **BRYANT** said that he had a report to hand in on the finances of the Council, prepared by Mr. E. R. Frere, the professional accountant selected by the treasurers in accordance with the resolution of the Council of Dec. 5th, 1900. He had three points to put before the Council, whether they should discuss the report *in camerâ*, whether they should have a shorthand writer to take a full report of what was said, or whether each member of the council should be asked to send in to the Finance Committee any suggestion he wished to make with reference to the subject of the report

Mr. **HORSLEY** said that as this was the expenditure of public money he thought it should be discussed in public

The **PRESIDENT**: Do I understand that no one suggests that this matter should be discussed *in camerâ?*

Dr. **PYE SMITH**: Yes, many of us.

Dr. **BENNETT**: I move that it be discussed *in camerâ.*

Dr. **PYE-SMITH**: I second.

Mr. **HORSLEY** said that he hoped the Council would not accept the motion, for he held strongly the opinion that the matter should be discussed publicly.

On a vote being taken 14 members voted for the motion, 13 against it, and four abstained from voting either way.

The Council accordingly went into *camerâ* for the consideration of Mr. Frere's report.

In this report Mr. Frere deals with the subject referred to him under several headings Under the heading of "The Relation of the Income and Expenditure of the Council and its Branches for the last Ten Years" he says:—

One of the chief difficulties in the situation is Section XIII. of the Act of 1858, which is as follows —

XIII —All moneys payable to the respective councils shall be paid to the treasurers of such councils respectively and shall be applied to defray the expenses of carrying this Act into execution in manner following, that is to say, separate accounts shall be kept of the expenses of the General Council and of those of the branch councils, and the expenses [illegible] keeping, printing, and pub- [illegible] shall be defrayed, under [illegible] of an equal percentage [illegible] branch councils; returns [illegible] ective branch councils at [illegible] ect of all moneys received by them, and the necessary percentage having been computed by the General Council the respective contributions shall be paid by the treasurers of such branch councils to the treasurer or treasurers of the General Council, and the expenses of the branch councils shall be defrayed, under the direction of those councils respectively, out of the residue of the moneys so received as aforesaid

[illegible] awn there were doubtless good reasons [illegible] on was inserted It was contemplated [illegible] be able to pay their way and have an [illegible] contribute the equal percentage rate, [illegible] e "residue" mentioned was calculated [illegible] ranch councils to exist. Owing, however, to the heavy annual demands of the General Council especially of late years, it has been found that the branch councils have in some years been obliged to realise portions of their invested funds in order to meet their own office expenses In the case of the Irish branch the reserve is exhausted

The following is a quotation from the report of the Special Finance Committee: "The fact, however, remains that the branch can only [illegible] and the Council and its branches looked upon as one body.

For the 10 years under review, 1890 to 1899, the total deficit, as shown by the report of the Special Finance Committee (including the Pharmacopœia), amounted to about £1100—or an average deficit of £110 per annum

This statement, however, is not a reliable guide when we come to consider the future.

Dealing with the same period, but excluding the Pharmacopœia, which is in future to be kept separate, it will be found that the first three years show an average annual surplus of upwards of £1140; the last three years show an average annual deficit of upwards of £1820; the actual deficit for the year 1900 being £1037 11*s.* 1*d.*

From this it is apparent that the surplus saved by the branch councils in former years is gradually diminishing a state of affairs which should not be allowed to exist, and which calls for earnest consideration and prompt action on the part of the Council.

Under the heading of "The Measures that Appear to be Desirable to place the Council's Finances on a Satisfactory Basis" Mr. Frere says:—

The simplest solution of the difficulty and, so far as I can see, the only means by which the Council can carry out its duties under the existing Act, without further reducing the surplus funds of the branches, lies in a very considerable reduction of the fees and expenses paid to the individual members of Council. The following are my recommendations: 1 That the fees for attendance be reduced from £5 5*s.* to £3 3*s* 2. That the additional fees for days of travelling be abolished 3 That instead of the present travelling allowances members should be recouped their actual disbursements under this head. 4. That steps should be taken to shorten as far as possible the sessional business. 5 It might be arranged that, except in special cases, the work of the committees should be done without fee.

I beg to add that I do not consider the present fee of £5 5*s* to be excessive considering the length of absence from ordinary duties which the meetings involve If these recommendations were carried out I estimate that there would be a saving in the expenditure of upwards of £1400 Unless measures such as the foregoing are adopted the only alternative is to materially increase the income, and the only possible way of doing this would appear to be by means of further legislation.

An Opinion as to whether Invested Funds are to be considered as Capital to be held intact.

When the Act came into force it would have been good policy to have capitalised all the retrospective fees and have treated the fund thus created as pure capital to be held intact. As the Act stands, however, all registration fees are clearly income and the present invested funds are accumulations of income.

As to the Method of Accounting.

I understand that some Members of the Council are of opinion that the form in which the accounts are issued is capable of improvement, and I have been requested to redraw those for 1900 with the object of showing clearly the result of each year's work and the financial position from year to year The accounts appear to me to have been prepared with great care and in full detail It is of course necessary from the treasurer's point of view that accounts containing this full detail should be prepared and filed, but as any difficulty there may be in following them probably arises from the publication of an excess of detail I have redrawn the accounts for 1900 in the form I should suggest for publication.

As to the Relations between the General Council and the Branch Councils under a New Act.

It appears to me from an ordinary business point of view that the relation between the General Council and the Branch Councils requires readjusting. When the Act of 1858 was drawn the present conditions were not foreseen, and no mention is made as to the accumulation of a surplus by the branches. I have already referred to the grant to the Irish Branch Council which, briefly stated, means that the Council have been obliged to assist the Irish branch at the expense of the English and Scottish branches Again, assuming that the General [illegible] registrations, which would materially increase the funds and [illegible]

When strangers were re-admitted no statement was made as to what had taken place *in camerâ.*

The Pharmacopœia.

Dr. **MACALISTER** presented the following report from the Pharmacopœia Committee:—

[illegible] Addendum had been sold

The collection of books relating to pharmacy and the Pharmacopœia has been arranged and catalogued under the supervision of Dr. Payne, to whom for this service and for the valuable additions he has himself made to the library the committee are much indebted. The committee also desire to express their thanks for welcome gifts of books from [illegible] room. At the invitation of the committee two important series of investigations have been undertaken, under the direction of Professor Greenish, in the research laboratories of the Pharmaceutical Society of Great Britain. The results have in part been published in the *Journal* of the society under the titles of "The Percentage Ash of Crude Drugs and their Powders" and "Determination of the Accuracy or Otherwise of the Solubilities given in the British Pharmacopœia." The researches when complete will be of great value in relation to the next revision of the Pharmacopœia. Other investigations undertaken at the instance of the committee in accordance with suggestions made at its conference with the representatives of the pharmaceutical societies are in progress, and the results will in due time be made public.

Dr. BRUCE asked for information as to how far the question of copyright came in and what steps had been taken to secure the copyright.

Dr. MACALISTER replied that the Executive Committee, to whom the matter had been remitted, had been active on the subject during the interval between this and last session, and so far as this country was concerned there was not the slightest doubt that the General Medical Council had the exclusive right of publication. There were good grounds for believing that the Act which applied to the United Kingdom was an Act of Imperial extent and applied to the colonies and India.

The report was received and entered on the minutes.

The Standard of Preliminary Examinations.

Dr. MACALISTER, on behalf of Sir John Batty Tuke, submitted a report of the Education Committee on the steps taken for raising the standard of preliminary examinations. This stated :—

The Education Committee, in pursuance of the authority given them by the Council "to take all needful steps to give effect to the recommendations and suggestions for the improvement of preliminary examinations," have, since the last meeting of the Council, continued their negotiations with the various examining bodies and have, in the case of several of these, arrived at highly satisfactory results With the valuable assistance of Professor McCormick, who has, in association with members of the committee, held conferences with various bodies in different parts of the country, they have come to an understanding with the authorities of Oxford, Cambridge, and Durham as to the enhanced requirements which, after Jan. 1, 1902, will be enforced in respect of their respective examinations The committee recognise with satisfaction the readiness with which the authorities of Oxford and Cambridge have met their wishes, and realise that the new conditions mark a considerable advance in the standard of attainments required of candidates who seek to qualify for the Students' Register by means of their local examinations The improvements to be made in the Durham certificate of proficiency examination are important, and may, for the present, be accepted as fulfilling the minimum requirements of the Council. But the committee are not satisfied that they bring the examination fully up to the level of the other University examinations in their revised form, and they hope that ere long a further advance will be made by the Senate of the University of Durham.

The junior local examinations of the University of Edinburgh and the University of Aberdeen and the preliminary examination of the Victoria University will, with the assent of these Universities, cease to be included in the list of recognised examinations on Jan. 1st, 1902

The College of Preceptors, the Royal Colleges of Physicians and Surgeons in Ireland, and the Educational Institute of Scotland have submitted proposals for new examinations intended to meet the increased requirements of the Council. The details of these examinations are still under the consideration of the committee It is recognised that a genuine effort is being made to bring them up to the required standard, but as fuller information on certain points is still desired, and as it is important that the three non-university examinations should be dealt with together and as nearly as may be on uniform principles, the committee have not yet been able to come to a final determination in regard to them. The committee hope that during the summer they may, by means of further conference and communication, arrive at a satisfactory arrangement with each of these bodies, whose willingness to coöperate with them they cordially acknowledge The list of examinations in the United Kingdom which are recognised as meeting the requirements of the Council will be finally adjusted by the committee and submitted at the November session of the Council

A communication has been referred to the committee in which it is urged on behalf of particular Indian students that the entrance or matriculation examinations of certain of the Indian universities should be replaced in the Council's list These examinations the Council in 1893, on the advice of the committee, decided to remove The grounds of the decision were twofold (1) that the examinations in themselves come short of the standard desired by the Council, and (2) that the universities by which they were conducted did not regard them as a sufficient qualification in arts for their own medical students, who were required in addition thereto to pass a higher examination in the same or similar subjects These grounds still exist and the Council's list accordingly in each case includes only the higher or qualifying examination in arts required as a minimum by the university itself. The committee are of opinion that it is not expedient to accept, on the part of Indian university students who take part of their course in this country, a lower standard of general education than that which is enforced by the medical faculties of their own provinces.

Dr. MACALISTER remarked that this report was an interim one and needed no comment. He moved that it be received and entered on the minutes.

Dr. REID seconded and the motion was agreed to.

Dental Education and Examination.

Mr. TOMES, for Mr. BRYANT, who was temporarily in th chair, presented the following report by the Dental Education and Examination Committee :—

An application has been received from the University of Birmingham for the recognition of its degrees in dentistry and has been referred to your committee by the Executive Committee. The University does not grant its degree in dentistry to any candidate who has not at least 12 months previously obtained a licence in dental surgery from some body legally entitled to confer such qualifications; it requires from such additional study and the passing of additional examinations, so that the degree is of the nature of a higher qualification and its recognition by the Council is governed by sub-section 6 of Clause 11 of the Dentists Act.

In this clause the Council is empowered to register or to remove from the Register "any additional diplomas, memberships, degrees, licences or letters held by a person registered therein, which appear to the Council to be granted after examination by any of the medical authorities in respect to higher degree of knowledge than is required to obtain a certificate of fitness under this Act." In addition to the production of his licence in dental surgery the candidate is required to produce evidence that he has attended the same courses and passed the same examinations as are required for the medical and surgical degrees of the university in the following subjects: chemistry and practical chemistry, physics and practical physics, biology, anatomy and practical anatomy, physiology and practical physiology. He is also required to have attended one course of lectures on medicine, one course on surgery, special courses on the surgery and medicine of the mouth, and pathology and bacteriology. Some of these courses will doubtless have been attended by the candidate in his curriculum for the Dental Licence, but the requirements of the Birmingham University are of greater stringency in that in all subjects of the first group he has to do all that is required of the medical student both in attendance and in examinations and in that in those of the second group he has to pass special examinations instituted for this dental degree. The final examination is conducted by the lecturers on the respective subjects in conjunction with an external examiner Without entering into further detail it is clear that the degree of Bachelor of Dental Surgery is intended to be, and in effect will be, a "higher qualification" in the sense of the clause in the Dentists Act referred to above. The degree of Master of Dental Surgery will be granted after not less than 12 months' interval upon the presentation of a thesis to be approved by examiners nominated for that purpose, and will be awarded or withheld according to their report. A technical difficulty exists in making any order at the present moment, inasmuch as, although an examination has been fixed for the latter part of this month, no examination has as yet been held.

An application from Mr B. C. Marriott Watson, a registered dentist in the Colony of Victoria, for registration as a colonial dentist has been referred to your committee by the Executive Committee. In the year 1898 two gentlemen holding qualifications of the Colony of Victoria were admitted to registration, but some questions subsequently arose with regard to the conditions under which their diplomas were conferred, these conditions having undergone several changes during the last few years. In the year 1900 another gentleman was registered in the Colonial List as registered in Victoria, but in this case also there were special circumstances which had to be taken into consideration, and none of these three registrations can be taken as affording any binding precedent.

In 1900 new and revised regulations of the Colony of Victoria were submitted to the General Medical Council and were referred to the Dental Education and Examination Committee and reported upon (Appendix, vol. xxxvii). It having been considered that the amended curriculum then submitted was not the full equivalent of our own the Council resolved (minutes, vol. xxxvii., p. 67): "That the Council is unable to recognise the diploma of the Dental Board of Victoria as entitling its holder to registration in the Dentists' Register of this country." The present application, which is accompanied by testimonials as to character, is for registration of a diploma conferred in 1890 in virtue of the candidate having passed the "Modified Examination" of the Dental Board of Victoria, and having been thereupon registered in Victoria in 1890 This "Modified Examination" your committee believe to have been one, applicable to persons who had been for a certain length of time in practice. Under these circumstances we cannot recommend the Council to order the Registrar to place the name of this gentleman on the Register.

This report was received and entered on the minutes, and, on the motion of Dr. MACALISTER, seconded by Mr. TOMES, it was resolved not to accede to the application of Mr. Marriott Watson for registration as a colonial dentist.

The REGISTRAR read a report from the Executive Committee on the dental business transacted since the last session of the Council who stated :—

The prescribed conditions having been duly fulfilled, the names of the under mentioned persons have been restored to the Dentists' Register, from which they had been erased in conformity with the provisions in Section 12 of the Dentists Act (1878).—David Anthony, Christopher F Badcock, Luther Bidlake, James N. Dunlop, Alfred C. Faulkner, Philip J. Harrington, George N. Lindup, W. Gerard Morgan, Edwin Robertshaw, and Stanley R Wakefield.

The committee has received an application for registration as a foreign dentist from a dentist holding a Brazilian diploma in dentistry granted after examination by the medical faculty of Rio de Janeiro in 1883. The application was not acceded to.

The report was received and entered on the minutes.

Prevention of Personation.

The Council went into committee to further consider a report from the special committee on the subject of prevention of personation.

Mr. HORSLEY mentioned that last session the Council had adopted the committee's first recommendation in the form following:—

> That in all cases where application is made for registration on the Medical or Dental Registers under exceptional circumstances the facts of the case shall be furnished in the form of a statutory declaration

On Recommendation No. 2 it was questioned by Sir CHRISTOPHER NIXON whether the Medical Act required *that the applicant should fill up the form of application in* his own handwriting.

Dr. MACALISTER asked if Recommendation No. 1 had been adopted by the Council.

Mr. HORSLEY replied that his recollection was that it was. Otherwise how could they have got to the second recommendation which now stood for consideration?

Dr. MACALISTER thought they had discussed Recommendation No. 1 and that before they came to a vote upon it the discussion had been adjourned.

Mr. HORSLEY did not agree. How could they have got to No. 2 unless they had passed No. 1?

Mr. BRYANT: There is no record of our having passed No. 1 and I rule that we begin again.

Mr. HORSLEY: Then I move the adoption of No. 1.

Mr. BROWN: If we go on to discuss this report would it not be better to have the recommendations entered on the minutes?

Mr. HORSLEY: They are already on the minutes.

Mr BRYANT: Go on, Mr. Horsley.

Mr. HORSLEY: My recollection is that Recommendation No 1 was discussed and agreed to by the Council and therefore I now simply move its adoption.

Dr. BRUCE seconded.

Dr. NORMAN MOORE thought that the Recommendation was going quite beyond the common usage of the universities and other licensing bodies who had to deal with such matters. It was quite uncommon for a fraud to be committed and he thought it was hardly desirable that they should introduce such a tone into their proceedings.

Mr. TOMES: The answer to that is that there have been cases of fraud.

After further conversation and reference to last session's minutes it was discovered that Recommendation No 1 had not only passed through committee but subsequently had been reported to the Council and then actually adopted.

Mr. HORSLEY thereupon proposed the adoption of Recommendation No. 2 which was in the following terms:—

> [illegible] all [illegible] up [illegible] ation [illegible] dec [illegible]

Dr. MACALISTER questioned whether it was within the powers of the Council to pass such a proposal as the Act of 1858 provided for the registration of persons *en bloc*, and any individual whose name had been sent up to the registrar by one of the licensing bodies might come and claim registration because of that alone. If any person did so he did not see how the Council or Registrar could resist.

Mr. HORSLEY pointed out that under Section 14 of the Act of 1858 the General Medical Council was authorised to make s[illegible] is section [illegible]

Dr. M[illegible] o make any by-laws it chooses unless they are contrary to the Act of Parliament.

Mr. TOMES regarded the recommendation as one that was not without importance, for there had been an actual case of personation which had come to light simply through investigation of the handwriting on the application form.

On the suggestion of Dr. NORMAN MOORE, Mr. HORSLEY put the recommendation into this form:—

> With the view to identification of applicants for registration on the Students' Register the form of application shall be filled up in the handwriting of the applicants.

The committee adopted this, and on the Council resuming Dr. MACALISTER reported their action.

For the remainder of the sitting the Council sat *in camerâ* considering Mr. FRERE'S report on the finances of the Council.

SATURDAY, JUNE 8TH.

The Council resumed to-day, Sir WILLIAM TURNER, the President, being in the chair.

The Finances of the Council.

In the minutes of the previous day's sitting with regard to the proceedings *in camerâ* an amendment was made to make it clear that the Council considered the report of the Special Finance Committee as well as Mr. Frere's report.

Mr. HORSLEY, after the minutes had been approved, moved that the representatives of the press be permitted to refer to the shorthand notes of the proceedings *in camerâ.* He thought that the Council went into *camerâ* under a misapprehension of the facts, for the Council simply reopened the discussion of last year on the report of the Special Finance Committee, a discussion which took place then in public. They were therefore in the curious position of having done one-half of their discussion on this subject in public and the other half in private. He of course had objected to their going into *camerâ* on the general ground that they were dealing with the expenditure of public money; a majority of one thought otherwise and therefore they went into *camerâ* Now he wished to suggest that nothing arose *in camerâ* that ought not to be published, and inasmuch as they had placed Mr. Frere's report upon their public minutes it seemed to him rather ridiculous and anomalous not to have an account of the discussion. He thought, therefore, that the representatives of the press should have access to the notes of the shorthand writer who was present

Dr. ATTHILL seconded the motion, saying that when he voted against the proceedings being public he did so under a misapprehension He thought that they were going into details, whereas the discussion was one which ought to have been public

The PRESIDENT asked Mr. Horsley how he proposed to give effect to his motion.

Mr. HORSLEY said that the shorthand notes would be transcribed and the transcript would be a document of the Council and he proposed that the representatives of the press should have access to it

The PRESIDENT: That is quite a new procedure.

Mr. HORSLEY I am quite aware of that and that is the reason why I brought it forward in this way.

Dr. GLOVER said that he sympathised with Mr. Horsley and thought they should go further than he proposed and publish the report like any other document of the Council.

Dr. MACALISTER thought that the proposal was not quite fair to those members who spoke while they were *in camerâ* and knew that they were speaking *in camerâ;* it was going behind their backs, in a sense. If members had known that the report of their remarks was going to be published they might very well have taken different lines. He did not think that without notice and after the fact anything of this kind should be done.

Dr BRUCE said that he thought this motion would set a bad precedent. He had no doubt that some of them did speak well knowing that they were speaking *in camerâ.*

Dr. PYE SMITH said that he did not vote for going into *camerâ* under any misapprehension. He took no part in the discussion and therefore it was indifferent to him in that sense whether or not the report was published, but in his opinion it would be wrong to publish the report.

Mr. HORSLEY said that he should like to reply to Dr. MacAlister's observation that something was being done behind somebody's back. He could not conceive anything being more open than his motion.

On a vote being taken nine voted for the motion and 16 against it, five members declining to vote and one member being absent.

The motion was accordingly rejected.

The Case of Dr Henry Ward Irvine.

The Council then took up the adjourned consideration of the case of Dr. Henry Ward Irvine, against whom on Nov. 29th, 1900, the following charge was found proved, viz:—

> That he accepted the office of consulting physician to the Consultative Medical and Surgical [illegible] tised in [illegible] widely circulated, setting [illegible] qualifications, and referring [illegible] ing practitioner, and solicit [illegible] at a reduced fee.

Dr Irvine attended, together with Dr. Hugh Woods, secretary of the London and Counties Medical Protection

Society, while the complainant in the case was represented by Dr. Bateman of the Medical Defence Union.

Mr. WINTERBOTHAM, solicitor to the Council, read the terms of the charge and stated that on Nov. 29th, 1900, at the conclusion of the deliberation of the Council on the case, the President informed Dr. Irvine that the charge which he had been required to answer had been proved to the satisfaction of the Council; that the further consideration of the charge proved against him had been adjourned until the May session; that the Council regarded the conduct complained of as being of a serious character; and that in adjourning the case it gave him an opportunity to reconsider his position.

Dr. IRVINE, addressing the Council, said that he would like to refer to a letter addressed to the Registrar of the Council by his solicitors two days after the inquiry of the Council. The letter was in these terms, viz. :—

1st December, 1900.

DEAR SIR,—We need hardly say that the decision at which your Council arrived on the 29th November was entirely unexpected by us and our client, and that the generality of their direction—viz., that he should reconsider his position before the next session of your Council in May next—places him in a position of serious difficulty. We have to-day discussed the matter with him with a view of carrying out the Council's direction. In so doing we have carefully considered the charge which the Council has held to have been established and (recalled, so far as we are able, the points which (from the questions asked) appear to have influenced the minds of the members of the Council; and we will proceed to deal with them in the following paragraphs. 1. It was suggested that the pamphlets which have been sent out (certainly without Dr. Irvine's approval) contained observations reflecting on the general practitioner and magnifying Dr. Irvine's skill and abilities. While admitting as he did that some paragraphs would bear such construction, he desires again to emphasise that he was not in any sense responsible for the circulation, much less for the preparation, of the pamphlets and at his request the Institution will not issue any more of these pamphlets and will so far as possible withdraw those already issued. 2. As to the circulation of the posters, we infer from certain questions asked that although these posters were honestly intended to be mere announcements of the inauguration of the new movement, their retention even by members of the Hospital Saturday Fund may be thought to be continued advertisement. In order to meet this objection the Institution have, again at Dr. Irvine's request, agreed to withdraw all those posters. 3 Criticism was directed to the title by which Dr. Irvine is described by the Institution in the above-mentioned pamphlets and posters. As, however, the Institution has agreed to withdraw these this objection is now removed. 4. We do not recollect that any objection was raised to the terms of the Institution's first report, but we are authorised to say that no further copies will be circulated. We think we have now (so far as the material at our disposal enables us) dealt with the points raised at the hearing but (confirming the evidence of Mr. Chamberlain) we are authorised by Dr. Irvine and the representatives of the Institution to say that he and they will carefully consider any suggestions which your Council may desire to make in relation to the duties discharged by their medical man. We write without delay, as we understand your Council remains in session only until Wednesday next and will not meet again until May.

Yours faithfully,
PINSENT AND COY.

The reply of the Council's solicitor to this letter was that the Council could not reopen the matter at that session; that the matter must stand adjourned. However, the committee of the Institution at once proceeded to carry into effect the offer made in the letter by sending round a man to all the firms which had received copies of these announcements, in order to collect all copies then existing. He might say that he was personally satisfied that the committee had carried out their promise in the most thorough and painstaking fashion. They sent round a second man in order to see that none of the announcements had been missed by the first man. In further considering his position he took the advice of the London and Counties Medical Protection Society, and he announced his resignation of his appointment in Birmingham to the Registrar of the Council in an informal way on March 4th and again during the month of April.

Dr. BATEMAN said that he had one or two questions which he should like to address to Dr. Irvine. He should like to ask him whether he would be surprised to learn that two of the pamphlets put in in evidence against him were still being issued by the Birmingham Hospital Saturday Fund.

Dr. IRVINE replied that he should be very much surprised.

Dr. BATEMAN asked whether he would be surprised to hear that his name-plate was still on the door of the Institution.

Dr. IRVINE said that he had ascertained that this was the case and had telegraphed to have the name-plate removed.

Dr. BATEMAN asked Dr. Irvine when he resigned the appointment.

Dr. IRVINE replied that it was on Feb. 21st. In answer to the President Dr. Irvine said that he no longer lived in Birmingham.

Sir WILLIAM GAIRDNER: Am I to understand that Dr. Irvine quite understood all the time that the gravamen of the charge was the objectionable advertisements and not the reduced fee?

Dr. IRVINE: I am glad to hear that that was the gravamen of the charge; that was my impression.

Dr. HUGH WOODS went into the witness-box and explained what had passed between Dr. Irvine and the London and Counties Medical Protection Society. Generally speaking, he said that Dr. Irvine had accepted the advice of the society and that advice had been to respect the wishes of the Council. Among other things the society advised him to sever his connexion with the Birmingham Institution. The society did not know whether the Council would consider it an offence to accept a salary from such an institution, but they understood the ground of objection chiefly to be the advertising. Dr. Irvine had severed his connexion with the Institution, had left Birmingham, and short of committing suicide he did not know anything more that he could have done than he had done. There was a quite definite intimation of intention to withdraw from the appointment on March 4th.

Dr. BATEMAN said that he only brought up the questions about the name-plate and the pamphlets so as to give Dr. Irvine an opportunity of repudiating what had been done.

The Council deliberated in private, after which the PRESIDENT announced to Dr. Irvine that they had resolved to proceed no further in regard to the charge.

Dr. IRVINE thanked the Council for their decision and the care with which they had gone into the case.

The Council and the English Royal Colleges.

The Council then proceeded to the consideration of the communications from the Royal College of Physicians of London and the Royal College of Surgeons of England with regard to the registration of medical students. In these communications the Royal Colleges announced that they could no longer require a registration of students by the Council as a condition of admission to examination for their diplomas, and presented certain of their regulations.

Dr. MCVAIL thanked Dr. Norman Moore for having furnished to members of the Council copies of the complete regulations of the Conjoint Board of the Royal Colleges. These regulations he proceeded to criticise. He said that they left the student free to go to schools some of which had not even been visited by representatives of the Royal Colleges. He objected to many of the institutions at which study was permitted.

Dr. NORMAN MOORE: Name.

Dr. MCVAIL: The list is as long as my arm, but to a large extent they are ordinary board schools.

Dr. NORMAN MOORE: General assertions of this kind ought not to be allowed and I call upon Dr. McVail to mention specific schools.

The PRESIDENT: I am given to understand that a committee of the Conjoint Board has revised the list of schools that was submitted to this Council about a year ago and that the list has been greatly diminished. So I am told, but I have not seen the new list.

Mr. HORSLEY: Might we have a copy of that list?

Dr. MCVAIL said that the indignation of Dr. Norman Moore was extremely interesting when they remembered that at the last meeting at which this subject was discussed the representatives of the Conjoint Board admitted that a number of the schools on the list had not been inspected at all.

Mr. BRYANT said that they admitted that a few of them had not been inspected and the number was diminishing.

Dr. NORMAN MOORE said that when these schools first came to be recognised they were not recognised as a part of medical study at all. At the time it was thought that the careful inspection which was carried out by the Science and Art Department at South Kensington was sufficient. After the inquiry into the South Kensington system the Royal Colleges proceeded to visit the schools for themselves. They took enormous pains and it was impossible to visit all the schools at once. They proceeded upon certain definite principles and to suggest that the Royal Colleges had been careless or neglectful was entirely unjust.

Dr. MCVAIL said that in the University Court of Glasgow, of which he was a member, they did not recognise a list wholesale and say that at their leisure they would make inquiries. The teachers and lecturers were all inquired about before they were recognised.

Dr. NORMAN MOORE said that that was exactly the case with the Royal Colleges.

Dr. MCVAIL said that he understood that the Royal Colleges first made out a list of recognised schools and inspected them afterwards.

Dr. NORMAN MOORE pointed out that the Royal Colleges first ascertained that the school had been recognised by the authorities at South Kensington. They accepted that recognition as, he maintained, they were justified in doing in the first instance.

The PRESIDENT asked Dr. McVail whether he intended to make a motion.

Dr. MCVAIL replied that he would move:—

> That the communications from the Royal College of Physicians of London and the Royal College of Surgeons of England, in so far as these relate to the courses of study accepted by them in the subjects of their first professional examinations, do not afford evidence that these courses of study are in all cases sufficient

He did not know yet, he said, whether the Conjoint Board had actually inspected every one of the schools or colleges other than recognised medical schools from which they received certificates of attendance. Unquestionably they had not done so six months ago. In Scotland they did not recognise any institution until it had been inspected and everything about it considered. He put his motion because the Royal Colleges laid down no definite instructions as to the length of the curriculum and because they accepted teaching from certain institutions about which this Council had no knowledge as to whether they were suitably equipped for the teaching.

Dr HERON WATSON seconded the motion.

Mr. HORSLEY asked if the representatives of the Royal Colleges would furnish the Council with a genuine list of the institutions which they recognised.

Dr. NORMAN MOORE said that he would furnish nothing in reply to any request so phrased. The word "genuine" was not to be used in this connexion. The Royal Colleges furnished every information asked for. Subjects of this kind were under constant consideration and discussion and every document furnished to the Council was genuine. He supposed that what Mr. Horsley meant was the latest list—the list up to the last date on which the subject was discussed.

The PRESIDENT: Then I understand that since the list was given in six months ago there has been reconsideration of it, and consequently the institutions named in that list are not quite the same as they were six or 12 months ago?

Dr. NORMAN MOORE: That is so.

Mr. HORSLEY: Might I ask for the date of that list.

The REGISTRAR: January 31st

Mr. HORSLEY: Might I ask for a copy of that list. It might help us

Dr. NORMAN MOORE: If I had supposed that this particular subject was to come before the Council I should have seen that a copy of the list was given to every member. I thought that the subject would not be before the Council. Is it really before us

Dr. MCVAIL: It is included.

The PRESIDENT: I hold that Dr. McVail is quite in order in raising this matter. The subject of whether the amended regulations of the Conjoint Board of England will secure a satisfactory education for persons desirous of entering the medical profession cannot be inquired into without reference to the Royal Colleges.

Sir WILLIAM GAIRDNER: We should have had ample notice of the discussion taking this particular form.

Dr. GLOVER: This is an immense extension of the subject that we thought we were going to discuss. If you are going into the efficiency of the Colleges, into their ability to give scientific education, you ought to give them notice.

The PRESIDENT: You are questioning my ruling Dr. Glover. I must say that looking at this matter without prejudice and simply as a man of business sitting in this chair I hold that the discussion raised legitimately emerges from the submission by the Colleges of their new regulations.

Mr. YOUNG questioned whether the Council was not losing sight of the most important matter that underlay the present proceedings His view was that the Council should discuss the matter as far as possible without reference to the Royal Colleges. The point which seemed to him to be fundamental, and more important than the question as to the satisfactory or unsatisfactory nature of a school wherever it might be situated, was the extremely far-reaching consideration which the new regulations brought forward The distinction between the new regulations and the old might briefly be summarised in this way—a student may attend instruction without being registered by the General Medical Council, although he may have passed the preliminary examination. That was why he said the regulations were far reaching The claim substantially was that the licensing bodies should have power to do what they chose There was a list of institutions reorganised by the Royal Colleges before the Council, but there was no guarantee that that list might not be added to. If so what became of the work of the General Medical Council in endeavouring and determining to raise the standard of education? It was really so much waste of time on their part. Before entering into details of the scheme suggested by the new regulations the Council should say whether the medical licensing bodies in future were to have the power to determine what scholastic institutions were and were not to be recognised as places in which suitable instruction could be obtained.

Dr. PETTIGREW said that the question before the Council was one of the most important that had come before them for many years. The Council had done the best they could to gradually raise the status of medical education and the English Royal Colleges had been parties to all the several steps which had been taken In their new regulations, however, they were introducing a disintegrating factor which, if agreed to, must produce a serious cleavage in every department of medical education These new regulations would virtually establish a four years' curriculum in place of the five years required by the Council. He hoped that the Royal Colleges would reconsider their position in regard to this matter.

Sir JOHN BATTY TUKE was of opinion that the action of the two Colleges simply meant reversion to the four years' course and if they were successful in attaining their object their action would be followed by a large number of the other licensing bodies It was an open secret that the Irish licensing bodies wanted to reduce the course to four years He had heard it stated so, and so far as the action of the Royal Colleges went it seemed that it was extremely probable and almost justifiable He might say that if the action of the Colleges was acceded to by the Council, or persisted in against the wish of the Council, the great universities would follow the example set by these Colleges. That seemed to be an inevitable result and the Council on the present occasion should confine themselves to that point rather than to the details of examinations. If it was proposed that the Council should take the extreme step of representing to the Privy Council that the examinations of the English Royal Colleges were not sufficient he thought they would mean business, but mere talk was of no good.

Dr LOMBE ATTHILL said that the Irish representatives looked upon the step proposed to be taken by the English Royal Colleges with great regret and if it were gone on with he was not sure what the result would be. He was, however, directed to say in the meantime that if the English Colleges did not abide by the recommendations and requirements of the General Medical Council the Royal College of Physicians of Ireland, which he represented, must take such steps as after due consideration they thought to be necessary.

Mr. BALL said that the Royal College of Surgeons in Ireland, which he represented, had come to no decision in the event of the General Medical Council taking steps to report to the Privy Council inadequacy of the examination of the English Colleges. He was strongly of opinion that the matter should be arranged definitely soon. His College had been in expectancy for the last 18 months and because of the absence of a decision on the part of the General Medical Council on this question they did not know in what direction to formulate plans.

Dr. NORMAN MOORE defended the action and position of the Royal Colleges. He thought that in this discussion they were unnecessarily raising too many side issues What was the difference which had caused the dispute between the General Medical Council and the Royal Colleges? There undoubtedly was a difference, but what was it? The Royal Colleges had all along supported the demand for the registration of students, and in former years had supported the General Medical Council in their resolutions to enforce it. The Royal Colleges had no desire whatever to disturb that arrangement. They wished to support the Council, but so far as instruction in chemistry, physics, and biology was concerned they claimed that they should have power to say at what institutions these subjects might be taught to possible or probable members of theirs. The Colleges insisted that they were entitled to lay down regulations of their own to secure that. The General Medical Council desired to raise the standard of education, so as to ensure that men or women entering the medical profession should have as thorough an education as it was possible to give or to obtain. That was exactly the object of the Royal Colleges. He, of course, was speaking for the Royal College of Physicians only, but he must say this, that he had never heard any opinion expressed or any suggestion made in respect to the Royal College of Surgeons which would disjoin that College from the College of Physicians in this special matter. Both were equally concerned with the improvement of medical education, with the maintenance of its standard. Any idea as to whether the lowering of the standard would add to the income of the Colleges or enhance their status had nothing whatever to do with the matter. When there was the same object in view why should there be this dispute? The Colleges contended that possible members of theirs might acquire instruction in chemistry, physics, and biology at places other than those on the list of the General Medical Council. They tried to find out what these places were, and they took into consideration the fact that there had been progress in the conduct and the teaching in public schools. For instance, far more science was now taught at Eton and Winchester than was taught in these schools some years ago. That surely ought to be taken notice of, for it had the most direct relation to the medical profession. The Royal Colleges, thinking so, were of the opinion that instruction in the three subjects in question might now be obtained at institutions other than universities or medical schools recognised by the Council. Instruction in these subjects must be obtained after passing the preliminary examination, and as that could not be taken until the student was 16 years of age there was no fear of any flooding of the profession with immature men. The Colleges had to consider the relation of the scientific education of the present day to their curriculum, and they had to ask: How was scientific education carried on in the medical schools and was scientific education always carried on in the most judicious circumstances? In certain institutions scientific education was undoubtedly not carried on in the magnificent way in which it was at Cambridge, but that was hardly a reason why it should be excluded from institutions that as closely as possible followed the University course. He certainly should like to see all candidates for the medical profession going to the universities, but really were there not in London schools that would give as good tuition in the three subjects in question? The answer to that question was that there were a good many, all of which had been examined and carefully inspected by the Royal Colleges. It was only fair that the list of these should be given to the Council, so that each individual institution should, if necessary, be criticised. The Royal Colleges did not include in their list what were called adventure schools. They laid down the rule that any school which they recognised as an institution in which scientific instruction might be given must be a public foundation. That was to say, it was in no sense to be a private institution; it must have a public governing body. They, moreover, insisted that its equipment should be satisfactory, and that included this provision—that there should be separate teachers for each of the three subjects of practical chemistry, physics, and biology. They refused to recognise an institution in which the same teacher taught both chemistry and physics. Such facts as these showed that the Colleges had taken great pains to ascertain whether there were in the schools included in their list the means of carrying on scientific education of the kind required by the Council, and they thought that they were doing a great public duty in thus encouraging scientific institutions. After referring to the Harris Institution in Preston and the Higher Grade Board School of Norwich—places which, he said, he had personally visited and approved of as places in which the education required by the Council for medical candidates could be obtained, he insisted that the Royal Colleges were doing a public duty in recognising the scientific teaching given in higher grade board schools. It was not sufficient for any member of Council to say that he objected to higher grade board schools. If there was to be objection at all it must take this form: "I object to the higher grade school at such and such a place." The R Colleges, he thought, wished for criticism. It was the duty the General Medical Council to criticise them as well as all the other licensing bodies. That was the way by which progress was secured. But where comments were made the criticism should be fair and just and should show that the Colleges wished to advance and to encourage education. The Colleges printed a list of institutions which should be recognised by them for the purpose of scientific education. So the whole difference between them and the General Medical Council was this: "What should these institutions be?" The Colleges were distinctly of opinion that they should be those which should most efficiently advance education. Both the Colleges and the Council had tried to find out these institutions. Why should they differ? The Colleges were of opinion that the Council went outside its functions when it dictated to the Colleges on such a detail as this. That was the opinion of the Colleges. These Colleges were assured that it was their duty to ascertain that the teaching, the place of teaching, the appliances for teaching, and everything which led to candidates becoming members of the Colleges, were sound and thorough. They should listen to no particular criticism on that. As a matter of fact they were willing even to retire from the Council's registration of students rather than give away the rights and responsibilities which by charter and Acts of Parliament had been entrusted to them. The General Medical Council he believed, had taken a false step in this matter. It had, he believed, misunderstood the action and position of the Colleges. There had been a suggestion that the Colleges did not wish to carry out the five years' curriculum. That was a mistake. The Colleges had carried out in the most loyal way the five years' curriculum ever since it was instituted in 1892. Never since that year had students been admitted to their roll without having gone through a five years' medical course after passing the preliminary examination in arts. This regulation, as a fact, had been enforced in the most thorough, straightforward, and rigid way. Therefore he hoped that the dispute would be settled amicably. It was of great importance to medical education that it should be. It was of great importance that the existing system of registration should be kept up, but he thought that it should be broken up rather than that the responsibilities of the individual bodies should be taken away. There was no feeling of defiance or anything of the kind on the part of the Royal Colleges to the Council. These Colleges wished to support the Council in every way. They felt that its work had been useful and that the difference between them was very slight, but at the same time they wished their own list of institutions to be accepted.

Sir CHRISTOPHER NIXON, speaking as the President of the College of Physicians of Ireland and representative of the Royal University of Ireland, thought that if the question of raising and maintaining the standard of education was properly put to the two English Royal Colleges there would be no difficulty in securing assent from them, because, as their representative had said, he believed that they had simply in view the General Medical Council's desire to raise the standard of education as respects candidates for the medical profession. He distinctly disagreed with anything that would mean a return to a four years' curriculum, and he insisted that the five years which the Council recommended and required should be rigidly adhered to.

The Council adjourned, leaving the debate unfinished.

MONDAY, JUNE 10TH.

The Council met again to-day, with Sir WILLIAM TURNER in the chair.

The Council and the English Royal Colleges.

The Council resumed the consideration of the communications from the Royal College of Physicians of London and the Royal College of Surgeons of England and the debate on Dr. McVail's motion:—

> That the communications from the Royal College of Physicians of London and the Royal College of Surgeons of England, in so far as these relate to the courses of study accepted by them in the subjects of their first professional examinations, do not afford evidence that these courses of study are in all cases sufficient.

Dr. MACALISTER said that there were one or two omissions in the very able and courteous speech of Dr. Norman Moore to which he desired to call attention. One of them was that the Council had laid down after much consideration the principle that a student who proposed to be called a medical student and to be registered as such should have finished his ordinary school education before his five years of medical study should have begun, and the point at issue was really this, Should they admit to the five years' curriculum students who had not finished their ordinary school education? However well equipped these schools might be for the school teaching of chemistry, physics, and biology, should they allow a student as his first year of medical study to spend a year partly in the study of these subjects and partly in the study of school subjects? Should they admit medical half-timers for the first year of medical study? The Council had pretty clearly indicated its desire that such a state of things should not be recognised. He would go further and point out that by recognising some of the institutions which had been proposed for recognition they should do something more pointedly to diminish the true value of the first year of medical study because they should admit institutions which gave instruction in these subjects at evening classes. If they did that there was nothing to prevent a student who desired to be called a medical student to put in his day and the freshness of it in the pursuit of some ordinary trade or profession and give his evening to what he would call the first year of his medical curriculum. He believed that in the old days, in Dublin at least, there was a group of students of this kind. These were not favourably regarded by the medical profession or the medical teaching bodies in Dublin and steps were taken to put the class to an end. Although interesting, it appeared to him to be more or less irrelevant to consider how good these institutions were. They might be very well equipped, indeed, for the purpose of giving boys a liberal education which should include science, but that was not the question. Were the conditions such as to require the serious study during the first year exclusively of the three subjects for which the institutions claimed credit? If that were not the case, however well the institutions might be equipped for other students, they were not fit for complete recognition as places for the first year of medical study. The other point omitted by Dr. Norman Moore to which he desired to call attention had reference to the preliminary examination in general education. It would be observed that under the new regulations of the English Colleges a recognised examination in preliminary education was to be one recognised by the Colleges and it was added that a list would be supplied on application. There was nothing about an examination on the list sanctioned by the Council. The Council knew that by slow steps and with great difficulty they had gradually been able, by the elimination of unsuitable examinations and by the raising of the standard of others, to bring up the condition of preliminary education to its present state, and all of them desired to see it raised still higher. But unless there was some central authority like the Council to see that these examinations were gradually raised it would be perfectly impossible for them to maintain the standard of liberal education which had always been the goal of the Council. If the English Colleges were to make a list of recognised preliminary examinations in arts it was of course equally open to every other body to claim the same right and insist upon it—a state of things which he could not regard as desirable. In his opinion the action of the English Colleges was fraught with great danger to the whole course of medical study and curriculum.

Mr. HORSLEY said there seemed to be an idea that this was a mere academic discussion with no practical interest for the bulk of the medical profession. That was a great mistake. Again and again the profession had expressed itself in the direction that the preliminary examination in arts must be raised to a level above that to which the General Medical Council had with [illegible] of the English Colleges there was hinged, although unwittingly, disloyalty to the principles of the Medical Act of 1886. If by the Act of 1886 there was a kind of consensus of opinion among the licensing bodies that they would, as it were, agree together for the conditions under which a student should pass immediately into the profession from his qualifying examination, surely there was also carried with that a consensus of opinion that the Council should represent the licensing bodies in the construction and regulation of the preliminary parts of the examination. He knew there were people who said that the Act did not give the Council a *locus standi* in dealing with these subjects. That was a matter for argument and he would not now enter into it, but certainly there was a feeling in 1886 that the licensing bodies, though possessing privileges by legal right, should nevertheless agree to sink the exercise of these privileges in order that they should all move together in the progress of medical education. Now this was an instance of the kind. No one denied the legal right of the English Colleges to do what they proposed. He was quite aware that the Council had been advised that there were points on which legal action could be taken if necessary, but he earnestly hoped that no such legal action would ever be taken in this matter, but, taking it simply from the point of view of ordinary fairness of agreement and coöperation, he did think that the English Colleges made a fatal mistake in medical education when they came forward and put into operation the rights which they appeared to possess but which other licensing bodies possessed and which other licensing bodies could have put into force if they had thought fit. Look at the consequences of their departure. The Council had gradually built up a system of registration of students. The Council realised the value of that registration and he did not suppose there was a teacher in any medical school who did not fully appreciate the value of that registration, and yet by an unfortunate accident that registration was made to suffer for this specific action on the part of the English Colleges. He had no doubt that these Colleges would have been very glad, as they took their share in the formation of the Students' Register, to avoid injuring such an important factor in the students' career, but the course that they decided to take had had this fatal effect. He was therefore really horrified to hear Dr. Norman Moore say that, weighing the one thing with the other, his College was quite prepared to ruin students' registration rather than forego the responsibilities of which he spoke. If the other licensing bodies did not think that their status and welfare were injured by foregoing their responsibilities he did not see why the Royal Colleges should have taken up this attitude. In his opinion they had done a great injury to medical education, and in spite of the eloquence of Dr. Norman Moore he thought that would be the way in which the medical profession would regard their action.

Dr. LITTLE asked from Dr. Norman Moore some information about the kind of chemistry taught in the institutions which it was proposed to recognise.

Dr. NORMAN MOORE said that the teaching of chemistry had always been a difficulty in connexion with medical education. One was constantly hearing complaints from the deans of schools upon the subject. In the institutions referred to he had no reason to believe that chemistry was taught in any different way from, say, his own school, St. Bartholomew's.

Dr. WINDLE pointed out that there were about 60 cities and towns in the list at present recognised by the English Colleges but no doubt with the advance of scientific teaching in schools the list would be enormously extended and it could not be very long before in every important town there would be a school coming up to the standard of those in the present list. That meant that there practically would be for the great majority of students presenting themselves for these diplomas a four years' course in a medical school and for all other students a five years' course in a medical school. Therefore, he considered this a death-blow to the idea which some of them cherished of a fifth year given up to clinical work. Last session Sir Dyce Duckworth relied on the test of examination, but examination should only be an incident in the career of a student, the essential thing being the carrying out of the curriculum. The kind of unity desiderated by Dr Norman Moore was rather a singular one. It was a unity in which the lion lay down with the lamb, but the lamb, if he might so designate the Council, was inside the lion. The Council was to agree with the Royal Colleges and then, and only then, all would be peace.

The PRESIDENT asked Dr. McVail whether he intended if his motion were carried to represent the matter to the Privy Council.

Dr. MCVAIL replied that if the motion were carried, as he hoped it would be, he would be perfectly content to leave the matter there until next session. The Royal Colleges and the other bodies would thus have an opportunity of understanding the position of the Council in the matter.

as to the height of the Sheik, but polydactylism nowadays is generally associated with dwarfism. Certain passages in this report betray some *odium theologicum* which is out of place in literature dealing with scientific matters and would be better eliminated.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JUNE 6TH.

The Post Office and Medical Provision.

CAPTAIN NORTON asked the Secretary to the Treasury, as representing the Postmaster-General, whether he was aware that an accident happened at Mount Pleasant sorting office on May 6th to a sorter causing him to faint; that in the absence of an attendant medical officer and of an ambulance this man had to be taken in a mail van to the Royal Free Hospital, Gray's Inn-road, nearly half an hour elapsing before he was attended to; and whether the Postmaster-General, in view of this and other accidents, and seeing that over 2000 men were employed at this office, would accede to the requests of the staff for a resident medical officer and give instructions for an ambulance to be kept on the premises.—Mr. AUSTEN CHAMBERLAIN said that the accident in question, which was due to a door swinging against the man's face, was not a serious one, and there was no record that the man fainted. It was reported to have happened at 8 2 P M., and as a cab could not be found at the minute the man was conveyed in a mail van to the Royal Free Hospital, where he arrived at 8 15 P.M. His wound was dressed and he started home in a cab at 8 30 P M. It did not appear, therefore, that any time was lost. It was not considered necessary to have a resident medical officer at Mount Pleasant; but the question of providing an ambulance litter (which, however, would hardly have been used on the occasion in question) was under consideration.

Coroners' Inquests (Railway Fatalities) Bill.

The order for the second reading of this Bill was discharged and the Bill was withdrawn.

FRIDAY, JUNE 7TH.

The Proposed Standard for Butter.

Mr HANBURY, President of the Board of Agriculture, in reply to a question on this subject, said that his department have already collected a considerable body of evidence to submit to the proposed committee upon a butter standard and he hoped to nominate the committee very shortly—at any rate, during the present month.

MONDAY, JUNE 10TH.

The London Water Question.

Mr. FORDE RIDLEY asked the President of the Local Government Board whether, in the event of the purchase of the London water companies under his proposed Bill, he would take steps to prevent the continuance of the system under which an increased rent for the use of water was charged on those houses where the rates had been increased under the quinquennial re-assessments although no increased supply or any alteration whatever in the supply might have taken place.—Mr. WALTER LONG replied that he was afraid he could not give any undertaking at the present time with regard to the subject of his hon. friend's question.

TUESDAY, JUNE 11TH.

Death Certification.

Sir JOHN KENNAWAY asked the President of the Local Government Board (1) if his attention had been directed to the report of the coroner's inquest, held at Birmingham on June 3rd on the bodies of 31 infants found in a cellar at the house of Mrs Knowles, and (2) seeing that a Select Committee reported in 1894 that the state of the law with respect to the disposal of the bodies of deceased infants and children was unsatisfactory and made recommendations in regard to its amendment, whether he could hold out hopes of introducing early legislation to deal with the abuses shown to exist.—Mr. WALTER LONG replied that the answer to the first paragraph was in the affirmative. The matter reported on by the Select Committee referred to was receiving his careful attention He should be very glad to be able to deal with it, but he was afraid he could not hold out any expectation of legislation on the subject during the present session.

Medical Officers of Health in Scotland.

The LORD ADVOCATE, in reply to Mr. WEIR, said that there are 278 medical men holding appointments as medical officers of health in Scotland. Of these, 61 possess a diploma in sanitary science, public health, or State medicine.

Civil Surgeons at the War.

Mr. SCHWANN asked the Secretary of State for War whether he had now received any answer to his telegram to Lord Kitchener with regard to the possibility of setting free and conveying home the medical officers who volunteered for service in South Africa, many of whom had been out from home much more than a year, exposed to heavy work and risk from contagion and otherwise.—Mr BRODRICK replied: Lord Kitchener has not yet been able to release civil medical officers apart from those whose engagements have terminated. If circumstances admit of it all possible consideration will be shown.

New Factory Legislation.

On the motion for the second reading of the Factory and Workshop Acts Amendment Bill Mr RITCHIE, the Minister in charge of the measure, gave an account of its main provisions. He explained that the existing law in the matter of ventilation applied only to the removal of noxious gases, dust, &c. There were, however, many cases in which workers were crowded in rooms heated by means of gas-jets where the air was never practically changed, and this Bill, while not laying down the particular form of ventilation, required that there should be sufficient ventilation in all such premises. As the Bill prohibited [illegible] employment of children in moving machinery. On the subject of underground Bill defined an underground place as a place where the room was three feet below the surface of the ground. It prohibit rooms being used for this purpose even if they were underground than three feet, but it placed on the local responsibility of seeing that where there were such places they be sanitary and licensed accordingly. The present regulations with dangerous trades were of an unsatisfactory character: might be separate rules for each factory and workshop in industry even where the conditions were exactly similar. One of worst features of the existing law was that the decision was left hands of an arbitrator, who had practically no decision was binding on the Secretary of State. The proposal Bill was that rules should in the first instance be made in draft the Secretary of State and for the entire trade; that all both employers and employed, might make with regard to them; and that the Secretary of State bound to take all objections into consideration, and advised, amend the draft rules accordingly. Before became operative there would be the fullest public inquiry arbitrator. The Secretary of State, however, would not be bound decision, but would form his own judgment; and, finally, the rules would be laid on the table of both Houses of Parliament. would, therefore, be ample public inquiry and the fullest responsibilit of the Secretary of State, as to which he attached the importance. Further, the Bill proposed to bring laundries within scope of the factory and workshop legislation; and with regard to preserving and fish curing, while it exempted these employments w regard to the hours of labour, it brought them under provisions.

Appointments.

Successful applicants for Vacancies, Secretaries of Public and others possessing information suitable for this column, invited to forward it to THE LANCET *Office, directed to Editor, not later than 9 o'clock on the Thursday morning of week, for publication in the next number.*

BERRYMAN, E. N., L.R.C.P. Lond., M.R.C.S. Eng., has been Medical Officer of Health of Llandovery, South Wales.

BOULTON, ARTHUR, L.R.C.P. Lond., M.R.C.S. Eng., D appointed Medical Officer of Health of Woodhall Spa,

BRAWN, H. E., M.R.C.S. Eng., L R.C.P. Lond., has Second Assistant Medical Officer at the

CLAY, T. W., L.R.C P., L.R.C.S. Edin., L.[illegible]P.S. Glasg., has appointed Certifying Surgeon under the Factory Acts for Holyhead District of the County of Anglesey.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

A WICKED ADVERTISEMENT.

WE have for long advocated that some check should be placed upon the pernicious advertisements of quacks and of quack medicines as appearing in the daily and weekly press, but, excepting possibly some of the effusions of abortion-mongers, we think that we have never seen a more wicked and disgraceful advertisement than the following which appeared in the *Daily Express* of June 6th. It is headed, "Awful Increase in Heart Disease—Have you the Symptoms?"

* * * * * * * *

Almost one half the people have heart disease. The trouble is they don't know it. .. ... It is no exaggeration to say that thousands of deaths might have been avoided had the victim known about our Heart Tablets. Pain is not the only symptom. Don't drop dead. ...... Sure signs of a diseased heart that cannot be mistaken are palpitation or fluttering, skipping a beat, dark specks in the vision, swelled feet or ankles (a positive sign), desire to sleep after eating, unnaturally cold hands and feet, tenderness, numbness, hungry or weak spells, painful to lay (*sic*) on left side, dropsy, neuralgia round the heart. If you have any of these symptoms don't delay a moment but write us at once. Relief is at hand. Read what others say about Oxien.

We have no hesitation in describing this advertisement as simply wicked, and we are surprised that any British journal can print such lies. The whole set of symptoms, although undoubtedly they can exist in patients suffering from heart disease, are in 999 cases out of 1000 simply due to chronic dyspepsia. When we add that the advertisement is adorned with a picture of a woman staggering away from a telephone through which she has just heard the message, "Your husband just died of heart disease," we have said enough to show that this advertisement practically seeks to get money by wickedly and basely playing upon fears which have no foundation. The advertisement emanates from Maine in the United States so the law cannot touch it, but surely such lies should not be permitted to appear in the press of this country.

HONORARY HOSPITAL APPOINTMENTS.

A SHORT time ago the governors of the Derby Royal Infirmary altered their rules and appointed an elective committee for the purpose of filling up vacancies in the honorary appointments. At an extraordinary meeting of the governors and subscribers of the Royal Albert Edward Infirmary, Wigan, on the 4th inst., the following alterations of rule was passed without dissent:—

Each honorary medical officer shall be elected by an elective committee which shall be appointed at each annual meeting and shall consist of the board of management and five members elected by the subscribers of the Hospital Saturday and Sunday Fund at their annual meeting.

The chairman of the board of management stated that this had received careful consideration at the hands of the board and he moved its adoption, with some alterations in other rules, which also had been considered carefully before submitting them to the subscribers. After the last election of a honorary medical officer the medical board strongly recommended a change in the method of election, and it is satisfactory to find the change readily accepted at the first opportunity by the subscribers. The medical board has four representatives out of six members on the board of management, and the senior honorary medical officer (Mr. Berry) was chairman during the past year and was again re-elected for the ensuing year at the first meeting of the new board appointed at the annual meeting.

ASTHMA AND GOUTY NEPHRITIS.

To the Editors of THE LANCET.

SIRS,—In reply to "General Practitioner's" query in THE LANCET of June 1st, p. 1582, about attacks of asthma coming on in the small hours of the morning in a subject of Bright's disease, I should say that the time of onset strongly suggests flatulent dyspepsia as the cause. I should treat him by light but solid food, restriction of fluids with meals, especially towards the end of the day, and the administration of a mixture of bicarbonate and sulphocarbolate of soda with ammonia, nux vomica, peppermint, and chloroform water at bedtime and on the occurrence of an attack.

I am, Sirs, yours faithfully,

S. L. B. W.

June 10th, 1901.

UNSOUND MEAT—HEAVY AMERCEMENT.

AT the Clerkenwell Police-court on June 10th William Kendall, butcher and sausage-maker, Chapel-street, Finsbury, was amerced in a penalty of £50 and £5 5s. costs for having for sale on his premises 96 pounds of unsound and unwholesome meat and sausages. Mr. Newman, medical officer of health, deposed that he inspected the meat and found it totally unfit to be consumed as human food.

WANTED—A HOME FOR EPILEPTICS.

To the Editors of THE LANCET.

SIRS,—I should deem it a favour if any of your readers could info
me of a home or institution for epileptics. As medical officer of
workhouse I have as patients two girls, about 16 years of age, and as
have neither proper attendants nor facilities for treating such cases
should like to try to get them into some suitable home. I have
doubt that my Board would agree to pay a reasonable sum fo
maintainance.

I am, Sirs, yours faithfully,

BROMI

June 10th, 1901.

WANTED—A HOME FOR THE TREATMENT OF INEBRIET

A MEDICAL MAN writes: "I shall be glad if you can put me into c
munication with the manager of any institute for the treatment
inebriety who would take a young man able to pay only a guinea
25s. a week for the accommodation." Any stamped replies receiv
at THE LANCET Office will be forwarded to the writer.

THE SWALLOWING OF FOREIGN BODIES.

IN the June number of the *Phonographic Record* Dr. James Adam
gives some instances of what he calls "accidental cures"—cases in
which, for instance, a goitre disappeared after a blow or a hernia
was cured by continued jolting. He concludes his paper with an
instance of death resulting from a supposed accident. He says:
"A well-known gentleman in a large Scottish town awoke one
morning with abdominal pain. He missed his false teeth from
his mouth. He was taken to hospital, abdominal section
done, and his teeth were not found." He was
were found under his pillow. He
medical friends, both well known
surprise each of them had had
swallowed false teeth without rem
patient was told to go home and lo
were found after two days' search
been put by a servant, in the other
moral is that when a patient swall
it and does not infer it from
course, applies to other articles
Most medical men who have hac
general hospitals must be familiar
more especially as regards children wh
bone connexion between the ring and
"comforters," immediately infer that it
tions to search for the foreign body at ho
from unnecessary surgical interference.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS" and not in any case to any gentleman who may be supposed to be connected with the Editorial staff It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS not used

MANAGER'S NOTICES.

TO SUBSCRIBERS

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W C , are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c , should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are —

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W C

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions Any demand for increased rates, on this or any other ground, should be resisted The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage

During the week marked copies of the following newspapers have been rece[illegible] *Mercury*, *Windsor and Et*[illegible] *Bristol* *Evening News* [illegible] *rertiser*, *Sunday Times* [illegible] *Mercury* *Harrogate Herald* [illegible] *ries and* *Galloway Courier*

AN ABSTRACT OF

The Croonian Lectures

ON

THE CHEMICAL SIDE OF NERVOUS ACTIVITY.

Delivered before the Royal College of Physicians of London on June 11th, 13th, 18th, and 20th, 1901,

By W. D. HALLIBURTON, M.D.,
F.R.C.P. Lond., F.R.S.,
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON.

LECTURE III.[1]

Delivered on June 18th, 1901

THE lecturer stated that in his two concluding lectures he proposed to deal with the more strictly pathological side of the subject. Chemical pathology was a comparatively new branch of science and it had a great future before it. He stated that the credit of opening up a new area of research—namely, the application of chemical methods to the investigation of nervous disease—should be largely given to his colleague, Dr. Mott. The three researches with which he proposed to deal were: (1) the chemical pathology of hyperpyrexia; (2) the chemical pathology of general paralysis of the insane; and (3) the chemistry of Wallerian degeneration.

THE CHEMICAL PATHOLOGY OF HYPERPYREXIA.

The experiments on this subject were described in detail. The lecturer said:

These experiments may be summed up by saying that they fully confirm the hypothesis that the physico chemical cause of death from hyperpyrexia is heat-coagulation of cell-globulin. When this constituent of cell-protoplasm is coagulated the vitality of protoplasm is destroyed, just as muscle loses its irritability when the corresponding proteid in that tissue is coagulated. The temperature at which such coagulation is most readily produced is 47° C. Such a temperature in animals is almost instantaneously fatal. But 47° C. (117° F.) is unknown in man. Nevertheless, proteids will coagulate at temperatures below their normal coagulating point provided the heating is continued long enough. In the case of cell globulin, coagulation can be produced by a temperature as low as 42° C. (108° F.). This chemical change in the brain substance can be demonstrated by experiments with saline extracts of that tissue or with the "surviving" brain of animals just killed. They are coincident with the histological (chromatolytic) changes in the nerve-cells which can be rendered evident by the use of the methylene-blue process. The expression "coagulation necrosis" employed by Marinesco for this appearance is therefore justifiable. Marinesco and others who have employed exclusively histological methods of research have naturally failed to grasp the chemical meaning of their observations and have consequently missed the connexion of the temperature necessary to produce these changes with that of the coagulation temperature of cell-globulin. Although the nerve cells are those which lend themselves most readily to the histological part of the research it is by no means improbable (looking at the wide distribution of cell-globulin) that many other cells of the body are affected by high temperatures in a corresponding manner; some varieties of what is called "cloudy swelling" are without doubt instances of coagulation necrosis.

THE CHEMICAL PATHOLOGY OF GENERAL PARALYSIS OF THE INSANE.

Dr. Halliburton stated that his work (in collaboration with Dr. Mott) on this subject had been previously published. He would therefore only describe it in general terms. He did so in order to lead up to the consideration of the third pathological subject which he proposed to deal with and which he reserved for his final lecture. He said:

The cerebro-spinal fluid removed from cases of general paralysis of the insane is much increased in quantity and takes the place of the atrophied brain material. It produces when injected into the circulation of anæsthetised animals (dogs, cats, or rabbits) a fall of arterial blood-pressure with little or no effect on respiration. This pathological fluid is richer in proteid matter than is the normal fluid, and among the proteids nucleo-proteid is present. The fall of blood-pressure is, however, due not to proteid or to inorganic constituents, but to an organic substance which is soluble in alcohol. This substance is precipitable by phospho-tungstic acid and by chemical methods it was identified as choline. The crystals of the platinum double salt, which when crystalised from 15 per cent alcohol are characteristic octahedra, form the most convenient test for the separation and identification of this base.

The nucleo-proteid and choline doubtless originate from the disintegration of the brain tissue and their presence indicates that possibly some of the symptoms of general paralysis may be due to auto-intoxication; these substances pass into the blood, for the cerebro-spinal fluid acts as the lymph of the central nervous system. Choline can be detected in the blood removed by venesection from these patients during the convulsive seizures which form a prominent symptom in the disease.

Normal cerebro-spinal fluid does not contain nucleo-proteid and the amount of choline is so small that it cannot be readily identified. Normal cerebro-spinal fluid produces no effect on arterial pressure; neither does the alcoholic extract of normal blood or of ordinary dropsical effusions.

The presence of choline in the pathological cerebro-spinal fluid and blood will not explain all the symptoms of general paralysis—for instance, it will not account for the fits just referred to. Its presence, however, is an indication that an acute disintegration of the cerebral tissues has occurred. If other poisonous substances are also present they have still to be discovered.

The proof that the toxic material is choline, rests not only on the chemical tests, but also on the evidence afforded by physiological experiments; the action of the cerebro-spinal substance exactly resembles that of choline. Neurine, an alkaloid closely related to choline, is not present in the fluid; its toxic action is much more powerful and its effects differ considerably from those of choline.

Physiological action of choline.—The doses employed were from one to 10 cubic centimetres of a 0.2 per cent. solution, either of choline or of its hydro-chloride. These were injected intravenously in anæsthetised animals. The fall of blood pressure is in some measure due to its action on the heart, but it is mainly produced by dilatation of the peripheral vessels, especially in the intestinal area. This was demonstrated by the use of an intestinal oncometer. The limbs and kidneys are somewhat lessened in volume; this appears to be a passive effect, secondary to the fall in general blood-pressure. The drug causes a marked contraction of the spleen, followed by an exaggeration of the normal curves, due to the alternative systole and diastole of that organ. The action on the splanchnic vessels is due to the direct action of the base on the neuro-muscular mechanism of the blood-vessels themselves; for after the influence of the central nervous system has been removed by section of the spinal cord or of the splanchnic nerves choline still causes the typical fall of blood pressure. The action of peripheral ganglia was in other experiments excluded by poisoning the animal previously with nicotine. Section of the vagi produces no effect on the results of injecting choline. There was no evidence of any direct action of the base on the cerebral vessels. Choline has no effect on respiration.

The effect of choline soon passes off and the blood-pressure returns to its previous level. This is due partly to the great dilution of the substance injected by the whole volume of the blood and may be partly due to the excretion of the alkaloid or to its being broken up into simpler substances by metabolic processes. It does not pass as such into the urine.

If the animal has previously received an injection of atropine, the effect produced by choline is a rise of arterial pressure, accompanied by a rise of the lever of the intestinal oncometer. This observation appears to be of some importance, for it shows how the action of one poison may be modified by the presence of another. This has some bearing on general paralysis, for the arterial tension in the early stages of that disease is usually high, not low, as it would be if choline were the only toxic agent at work. After a succession of fits the tension sinks, and this may be explained as a result of choline action.

---

[1] Abstracts of Lectures I. and II. were published in THE LANCET of June 15th, p. 1659.

Physiological action of neurine.—The doses employed varied from one to five cubic centimetres of a 0·1 per cent. solution. These were injected intravenously. Neurine produces a fall of arterial pressure, followed by a marked rise and a subsequent fall to the normal level. The effect of neurine on the heart of both frog and mammal is much more marked than is the case with choline; in the case of both choline and neurine the action on the heart is antagonised by atropine. The slowing and weakening of the heart account for the preliminary fall of blood-pressure. The rise of blood-pressure which occurs after the fall is due to the constriction of the peripheral vessels, evidence of which was obtained by the use of oncometers for intestine, spleen, and kidney. It produces a marked effect on the respiration. This is first greatly increased, but with each successive dose the effect is less, and ultimately the respiration becomes weaker and ceases altogether. The animal can still be kept alive by artificial respiration. In large doses neurine acts like curare on the nerve endings of voluntary muscle. It should be mentioned that in the cases of brain atrophy referred to the cerebro-spinal fluid was removed as a rule soon after death. Specimens removed during life by lumbar puncture give, however, the same results.

[The lecture was illustrated by a number of lantern slides to show the histological changes in nerve-cells referred to, and also the graphic records of the experiments on blood-pressure, &c., in connexion with choline, neurine, and cerebro-spinal fluid.]

LECTURE IV.

Delivered on June 20th, 1901.

The Chemistry of Nerve Degeneration.

The concluding lecture dealt with the chemistry of Wallerian degeneration, the third of the pathological questions to which the lecturer had alluded at the commencement of his previous lecture. Dr. Halliburton said:—

It has been now shown that in the disease general paralysis of the insane the marked degeneration that occurs in the brain is accompanied by the passing of the products of degeneration into the cerebro-spinal fluid. Of these, nucleo-proteid and choline are those which can be most readily detected. Choline can also be found in the blood. On continuing work in this direction it was found that this is not peculiar to the disease just mentioned, but that in various other degenerative nervous diseases (combined sclerosis, disseminated sclerosis, alcoholic neuritis, and beri-beri), choline can also be detected in the blood. The tests employed to detect choline are mainly two: (1) a chemical test—namely, the obtaining of the characteristic octahedral crystals of the platino-chloride from the alcoholic extract of the blood; and (2) a physiological test—namely, the lowering of blood-pressure (partly cardiac in origin and partly due to dilatation of peripheral vessels) which a saline solution of the residue of the alcoholic extract produces; this fall is abolished or even replaced by a rise of arterial pressure if the animal has been atropinised. It is possible that such tests may be of diagnostic value in the distinction between organic and so-called functional diseases of the nervous system. The chemical test can frequently be obtained with 10 cubic centimetres of blood. A similar condition of the blood was produced artificially in cats by a division of both sciatic nerves and is most marked in those animals in which the degenerative process is at its height, as tested histologically by the Marchi reaction.

The Marchi reaction is the black staining produced by Marchi's fluid, a mixture of Müller's fluid and osmic acid, after the tissue has been previously hardened in Müller's fluid. Osmic acid by itself stains the medullary sheath of fresh healthy nerve-fibres black, but if the healthy nerve-fibres have been previously treated with a chromic solution like Müller's fluid they take on a greenish-grey colour with Marchi's fluid. Neutral fat, on the other hand, such as in ordinary adipose tissue, is stained black by Marchi's fluid under all conditions and the degenerated fat which appears in Wallerian degeneration resembles the fat of adipose tissue in this respect. The chemical explanation of the Marchi reaction is the replacement of phosphorised by non-phosphorised or neutral fat. When the Marchi reaction disappears in the later stages of degeneration the non-phosphorised fat has been absorbed. These facts were established by chemical analysis of the nerves.

The axis cylinder participates in the fatty degeneration; and the multiplication of the nuclei of the primitive sheath is first noticed about the eighth day and is possibly due to the irritation set up by the presence of the products of disintegration.

The main facts regarding the experiments in animals may be summarised as follows. A series of 18 cats was taken; both sciatic nerves were divided, and the animals were subsequently killed at intervals varying from one to 106 days. The nerves remain practically normal as long as they remain irritable—that is, up to three days after the operation. They then show a progressive increase in the percentage of water and a progressive decrease in the percentage of phosphorus until degeneration is complete. When regeneration occurs the nerves return approximately to their previous chemical condition. The absorption of the fatty products occurs earlier in the peripheral nerves than in the central nervous system. This confirms previous observations by Mott and Barratt on human spinal cords, in which unilateral degeneration of the pyramidal tract by brain lesions produced an increase of water and a diminution of phosphorus in the degenerated side of the cord which stained by the Marchi reaction. The main results of the experiments on animals are given in the following table:—

Days after section.	Cats' sciatic nerves.			Condition of blood.	Condition of nerves.
	Water.	Solids.	Percentage of phosphorus in solids.		
Normal.	65·1	34 9	1·1	Minimal traces of choline present.	Nerves irritable and histologically healthy.
1–3	64·5	35 5	0·9		
4–6	69·3	30·7	0·9	Choline more abundant.	Irritability lost; degeneration beginning.
8	68 2	31·8	0·5	Choline abundant.	Degeneration well shown by the Marchi reaction.
10	70·7	29·3	0·3		
13	71 3	28 7	0·2		
25–27	72 1	27·9	Traces.	Choline much less.	Marchi reaction still seen, but absorption of degenerated fat has set in.
29	72 5	27 5	0·0		
44	72·6	27·4	0·0	Choline almost disappeared.	Absorption of fat practically complete.
100–106	66·2	33·8	0·9		Return of function; nerves regenerated.

Our chemical knowledge of the process of Wallerian degeneration is thus mainly limited to what occurs in lecithin, the main constituent of myelin. This substance is broken up into its constituents, and each of these is in time removed by absorption. The products of disintegration are four in number: (1) choline—this is removed first and can be detected for a time in the blood; (2) phosphoric acid—this disappears next; and (3 and 4) fatty acid and glycerine—these are the elements of a neutral fat and the fat so formed resembles other neutral fats by giving the black Marchi reaction. In time, however, this is removed also. In the removal of the fat, certain cells, probably the hypertrophied cells of the neurilemma, can be seen microscopically to play a phagocytic rôle.

Noll has shown another interesting fact in connexion with "disuse atrophy"—that is, the change which occurs in the central end of a divided nerve before regeneration has occurred. Here there is also some diminution in the amount of protagon, though not nearly so great as in the peripheral end of the nerve.

[The lecture was illustrated by a number of lantern slides, to show the relationship between the histological and chemical changes which occur in divided nerves. Other slides were reproductions of the tracings showing the effects upon arterial pressure of the choline separated out from the blood of the cases of nervous disease mentioned, and from the blood of the cats operated on. These and others will be reproduced and full details of all the experiments will be given when the lecturer publishes these lectures in a separate form, which he hopes to be able to do shortly.]

Three Lectures

ON

THE PRACTICAL POINTS IN THE TREATMENT OF THREATENED ASPHYXIA.

Delivered at the Medical Graduates' College and Polyclinic, Chenies street, W.C.,

By ROBERT L. BOWLES, M.D. St And., F.R C.P. Lond.,

CONSULTING PHYSICIAN TO THE FOLKESTONE HOSPITAL, PHYSICIAN TO ST ANDREW'S CONVALESCENT HOME.

LECTURE I.

GENTLEMEN,—The object of this short course of lectures is to engage your attention on a subject apparently simple and to show that on closer consideration it is a subject wide and all-embracing. To organic nature air is life, and the prevention of a due and proper supply implies either immediate or slow impending death. The regular, orderly, vital and chemical processes necessary to the well-being of plants and animal life can only continue by a supply of oxygen in a suitable form, and that form is supplied to us by nature as "atmospheric air." Now this air, so freely supplied, is introduced to the bodies of men and animals by the air passages, and it is, of course, essential that those passages should be free and safe from obstructions, partial or complete. It is this department, the department of respiration, with which I shall principally have to occupy your attention. Inasmuch as all obstructions, whatever their source, must immediately depend upon mechanical or physical causes, my subject might well be entitled "The Physics of the Upper Air Passages and their Relations in Health, Accident, and Disease."

The *nature* of atmospheric air I need not dwell upon; you all realise as men of experience that it is in the concrete a proportionate mixture of nitrogen, oxygen, and argon, a small quantity of carbonic acid and an ever-varying proportion of vapour and incidental gases, and that it suspends and has mingled with it endless organisms and atoms, ordinarily inappreciable to our senses, but doubtless having relations with our bodily welfare so far unknown and inscrutable With the physics of our bodies it is different; here we must at once closely question the relations of part with part, their size, shape, and form, and their interactions. We must, in short, "look up" our anatomy and refresh our minds with the physiology pertaining to respiration.

The tendency of modern medicine is to drift more and more exclusively into the due and proper application of the laws of physics to the wants and derangements of suffering humanity, to make in short more truly the man of physics, the physician of to-day, and so more like our forefathers in the days of Hippocrates, when heat, light, rest and repose, exercise, gymnastics, baths, friction, and suitable food and drink were the remedies principally relied upon by the great leaders of the healing art in the relief and cure of disease. Dr Vivian Poore in his admirable Harveian oration says: "Greek philosophy, and Greek medicine as a part of it, was grounded on the solid basis of observation. It was the product of sound minds trained in the pure atmosphere of liberty and nurtured in sound bodies developed by manly exercises" Later he says: "Darkness gradually overwhelmed the enlightenment of the Greeks. Philosophy gave way to mysticism; reason was swallowed up by superstition, and inquiry was strangled by authority. Men engaged in endless speculations and tried by fire and sword to settle questions which could not be solved by reason—questions which now barely serve to furnish a little damp ammunition for the political pyrotechnist. Intellectual training was almost limited to dialectics, and men could argue so nimbly and with such faultless logic from phantom premisses as to justify the later witticism that language was given us to conceal our thoughts. Under these blighting influences medicine withered almost to death, and the physicians of the fourteenth century were more ignorant than those of the first century. It is tolerably certain, to take a concrete example, that the beloved companion of St Paul had a more extended and more scientific grasp of medicine than the immediate predecessors of Vesalius and Harvey."

All our organs of special sense are concerned with the relations of physics to our bodies and with their proper application—indeed, it would appear as if the senses could have no other purpose—and the instruments of the physician as well as of the surgeon are employed to aid and to strengthen the senses in their work: lenses and microscopes for the sight, stethoscopes and pleximeters for the hearing, thermometers for recording the bodily temperature, and so forth, apart from the supports, splints, bandages, and the many and highly perfected instruments of the practising surgeon.

The relations of the laws of physics to the derangements which may occur in the *respiratory* processes in health, accident, and disease are of extreme interest and importance. A child in the midst of play and happiness is seized with dyspnœa, apnœa, and asphyxia ending in death; a pea is found in a large bronchial tube, or a morsel of food or other foreign body in the larynx, and so the disaster is explained. Another child is only too well covered with bed-clothes and in the morning is found smothered in bed. A man has fallen by the wayside and is first seen in profound coma with heavy stertorous breathing and so is being slowly but indirectly suffocated by the paralysis consequent upon a cerebral hæmorrhage or by an injury to the cranium giving rise to compression of the brain; or a patient has just been rescued from the water and is dying on the river bank from suffocation caused by the retention of watery foam in the lungs and air passages. Others may be suffocating from the coagulum of hæmoptysis or from croup, pneumonia, bronchitis, or other diseases within the air passages, and yet others from mechanical pressure outside the chest, or outside the principal air ways, as in aneurysm, new growths, or glandular enlargements. We have all seen cases of these different forms of respiratory catastrophes and we have all applied the principles of physics in their relief, but inasmuch as I have for over 40 years given very special attention to this subject and have made it an experimental study I am not without hope that I may excite in you a new and greater interest in it for the future, and that you will find the principle involved "an ever present help in time of trouble."

"Searching out the secrets of nature by way of experiment" was the guiding principle of the immortal Harvey, and "do not think but try" was equally the guiding principle of that wonder of the more recent past, John Hunter. In connexion with the relative values of observation and of experiment the great Virchow in his "Cellular Pathology" says: "By observation is obtained the verification of facts; by experiment are acquired the precise methods for re-proving them. Above all, observation is directed on the ultimate elements accessible to the senses of man; medical science is divided into an enormous heap of individual facts which appear to confuse the minds of many But for him who dominates the facts on which the new views are founded an order is revealed that, departing from a general biological principle, permits the new discoveries to be connected according to their value, according to their mutual relations, into a scientfic whole." With views similar to these and with a similar object, under the able supervision of that brilliant physiologist, the late Dr. Marshall Hall, our first experiments were instituted at St George's Hospital to *re-prove* by precise methods certain facts observed in the drowned and to investigate the then accepted methods for resuscitation.

It was in the autumn of 1855 that I first had the privilege of knowing Dr Marshall Hall He was then suffering from a malady which he knew must prove fatal; not only was he in constant suffering but in constant danger of sudden death from spasm of the glottis, or of a slower death from starvation, and yet he was at that time pursuing with the utmost ardour two important physiological inquiries—the one, in consequence of the notorious "Palmer trial," on the detection of strychnine in solution by its extraordinary influence on the spinal system of frogs, and the other on the effects of suspended respiration and the best means of restoring the patient affected by that suspension. It was at this time that I was invited to join Dr. E. Long Fox, now of Clifton, and the late Mr. Charles Hunter in an inquiry on the amount of air which could be introduced into the chest by alternate pressure on and relaxation of the chest-walls—to test, in fact, the value of Leroy's principle. Out of this inquiry arose many unexpected and interesting observations which were at once made the subject of further experiment by which principles of a far-reaching character were ultimately established and made applicable in the treatment of many forms of accident and disease as well as in suspended animation from drowning. In consequence of the state of his health Dr. Marshall Hall was not able to be present at any of our experiments in the post-mortem room; so each of us took separate notes, made our observations on the work we had done in the day quite independently, and gave suggestions for further work. These were separately posted to Dr. Marshall Hall and the next day we all went to tea with him, discussed our proceedings, and took down his suggestions for the following day's work.

This little preliminary history I think necessary to the true understanding of our subject. Dr. Marshall Hall recognised three main facts—first, that the warm bath was a slow poisoning process if used before respiration was established; secondly, that drowning was a form of apnœa, but that the forcing of air into the patient's mouth or nostrils had not proved a successful method of introducing air into the lungs; and thirdly, that the elasticity of the chest-walls ought to be sufficient to introduce the amount of air required to support life, and it was to prove this last proposition that we were requested to perform the necessary experiments. It will now be convenient shortly to demonstrate the nature of those experiments, the anatomical relations of the parts concerned, and the physiological and pathological indications of the experiments themselves. The mode of procedure was the following and was published at the time. "An indiarubber tube was inserted into one nostril, the opposite one, with the mouth, being closed and rendered air-tight by plasters, bandages, &c. The free end of the tube was now attached to a glass syphon containing a small quantity of water in its bend, and to the opposite end of this syphon was fastened an oiled-silk bag made in the form of an intestine, to which it was similar in appearance and calibre when inflated. This bag, when full, contained 40 cubic inches. The water in the syphon acted as an index of the direction of the air in its passage to or from the bag, or, as we have called it in the experiments, the oiled silk tube. It was the amount of air expired into this tube on pronation and pressure which enabled us to compare it with the natural expiration of 30 inches, for when the tube was half-filled, which was easily proved by pressing the air towards its closed extremity, we inferred that we had 20 cubic inches in the tube, and so on. We did not pretend to perfect accuracy as to the amount, but it must be an exceedingly near approximation to the truth. I think you will also see in these experiments proof that though the supine position does not in every case prevent the passage of air it does so in a large proportion of cases; and if it does so in one case only that appears to me quite reason enough why that position should be avoided.

"*Subject 1.*—A male subject, much emaciated, about 50 years of age, and six feet in height; the body was not quite cold, and cadaveric rigidity had but partially come on; he had been dead 10 hours. The apex of the tongue reached the incisors, and the body of the tongue was at the floor of the mouth, so that a considerable space existed between its surface and the roof of the mouth. Some fluid was seen at the back of the fauces and on laying the body on its face a large quantity of fluids and solids from the stomach made their escape.

"*Experiment 1.*—Semi-rotation, prone and lateral. In the former position the tube was half filled with air, and in the latter it was instantly emptied.

"*Experiment 2.*—By alternate pressure and relaxation on the thorax (the subject supine) the same result was obtained as in Experiment 1.

"*Experiment 3.*—Semi-rotation, prone and lateral, was again had recourse to and with the same result as before.

"*Experiment 4.*—Alternate pressure and relaxation on the thorax in the supine position. *This time, not the slightest inspiration or expiration could be obtained.* On removing the coverings of the mouth the tongue was seen to be in the same position as when we began, but *there was again fluid in the pharynx.*

"*Remarks.*—This case demonstrates how, in the *supine* position, fluids in the stomach might interfere with respiration; for in Experiment 2 a good result was obtained, no fluid being in the pharynx; but after the further movements of Experiment 3 grumous fluid had been ejected from the stomach, filling up the pharynx and totally preventing the passage of air into or out of the trachea. This case also shows that the epiglottis does not in all cases cover the glottis in the supine position."

On the publication of my letter and report[1] Dr. Marshall Hall issued a set of rules for the application of the "Ready method." These were at once adopted by the rank and file of the profession—that part of it, indeed, which almost exclusively attended to such emergencies—and cases of the most wonderful recoveries were published week by week in the medical press. THE LANCET wrote laudatory articles, changed the name of the system to the "Marshall Hall method," and "Deodatus" would have been the lowest title accorded by the great body of the profession to Dr. Marshall Hall at that particular time. Meanwhile the Royal Humane Society, under the ægis of the great Sir Benjamin Brodie, held superbly aloof, stuck to the comforts of the warm bath, and would only touch the new method with the tips of its fingers—a healthy *non possumus*, as I think, in the teeth of such a threatened revolution, although the action of the society was opposed to the views based on our experiments. But more and more wonders were week by week related, until in 1858 Dr. H. R. Silvester came forward with a newer method still and called a halt in the general acclaim. Dr. Silvester repeated and confirmed our experiments on the dead body—viz., that compression and relaxation of the chest-walls gave rise to a movement of air into and out of the lungs, but he claimed, and rightly claimed, that more air could be introduced by extending the arms upwards and expanding the chest. This fact had already been well known to us in the course of our experiments, but it had also been clearly demonstrated by us that inasmuch as the supine position of the body was essential to the proper application of the arm-extension method of treatment it was quite useless as a recommendation for use by the general public in the resuscitation of those apparently drowned, and it was for the use of the life-saving societies and the non-professional public that our experimental inquiry had been conducted.

You will at once see, after what I have told you about throat, laryngeal, and bronchial obstructions from gravitation, the importance of not in any sense permitting the public to put their trust in any method which implied the necessity of the supine position of the body. Dr. Silvester says that by his method 10 times more air was respired than by the Marshall Hall method, but I cannot find in the first or third edition of his pamphlet any evidence of his having *measured* the amount of the air; the only point that he demonstrates is that water rose and fell in a bent barometer tube as in our syphon, so that in that way only a cubic inch of air or less could have been acted on. I am quite sure, however, that more air is respired by the raising of the arms, for we, as I have said, found it to be so long prior to Dr. Silvester's appearance in the field.

But the *amount* of air respired is entirely a secondary consideration; people nigh unto death or in states of syncope require very little air indeed to keep alight the spark of life. The matter of primary importance is to ensure a free and open air way, to see that there is no obstruction anywhere *en route*, and that nothing is present in the lungs to prevent the air from penetrating freely the finest of the bronchial tubes and from reaching the alveoli themselves. From dissection I have shown how easy it is in the supine position for the tongue to fall back into the pharynx and to lie in comatose or syncopal conditions, with its epiglottis on the posterior wall of the pharynx and so to block the air way, and for fluids or food to collect and to gravitate in the buccal and nasal cavities, and by our very attempts to save life in this position of the body for fluids or solids to be inspired or forced into the tubes and air cells of the lungs.

In drowning beyond and above all accidents affecting the respiratory process is the prominent and palpable fact that the lungs are stuffed and filled with froth, fine foam, and fluid varying in quantity, quality, and consistence, according to the circumstances attending the disaster. This is a fact attested by all the leading pathologists of Europe and about which there can, I think, now be no doubt whatever. Granting this, we see at once that Dr. Silvester, instead of providing for the clearance of the lungs, so directed his experiments as to determine the greatest amount of air which could be introduced into lungs already clear and in a normal condition, a proceeding which, for reasons now obvious to you, did not apply to cases of drowning; and, moreover, he introduced the air through an opening directly into the trachea, thus doing away with the protective influences of the glottis in the living body and avoiding the danger of blocked air ways in the dead subject under experiments. However, his "method" was two years newer than ours, which is much to say in these days of haste and hurry, and the assumption that by it more air could be introduced into the chest attracted so much attention and gave rise to so much discussion that the Royal Medical and Chirurgical Society was induced to appoint a committee to adjudicate on the relative merits of the methods of resuscitation then in vogue for the treatment of apnœa and drowning. That committee, which had for its chairman Dr. C. J. B. Williams and included such men as Dr. Kirkes, Dr. George Harley, Dr. (now Sir) John Burdon Sanderson, Dr. Brown-Séquard, Dr. Hyde Salter, Sir Edward Sieveking, and Mr. Savory, was certain to uphold the honour of the society which those great names represented and certain also to command the confidence of the life-saving societies and the profession generally. Their report was read at the society on July 1st, 1862, and was published in Vol. XLV. of their Transactions and in THE LANCET.[2] The details of the experiments, although most interesting and instructive, for brevity's sake I omit. The committee first investigated anew the phenomena of apnœa in its least complicated form —viz., when produced by simply depriving the animal of air—and next the subject of drowning, especially as to the period during which an animal could be submerged and "yet recover without the aid of artificial respiration." Next the treatment of apnœa was considered, and next the experiments on the dead subject and a treatment of the apparently drowned based on those experiments was suggested, and it is with these that we shall for the moment chiefly concern ourselves. The report says[3]: "These experiments satisfactorily show that the difference between apnœa produced by plugging of the trachea and that brought about by drowning is not due to submersion, to depression of temperature, or to struggles, seeing that the two animals are placed under similar conditions, with this most important exemption—that in the one case a free passage of air out of the lungs and of water into them is permitted; in the other the exit of air and the entrance of water are prevented. There can be no doubt that both these circumstances are concerned in producing the difference in the results of the two experiments; but that the fact that animals do not recover after so short a period of immersion is mainly due to the entrance of water and the effects thereby produced seems to be established by the following considerations: The condition of the lungs, as revealed by the post-mortem examination. On examining the lungs of the animals deprived of air by plugging the trachea they were found simply congested, but in the animals drowned not only was the congestion much more intense, accompanied with ecchymosed points on the surface and in the substance of the lung, but the air-tubes—[and there, gentlemen, is the conclusion of the whole matter]—were completely choked up with a sanious foam, consisting of blood, water, and mucus churned up with the air in the lungs by the respiratory efforts of the animal. The lung substance, too, appeared to be saturated and sodden with water which, stained slightly with blood, poured out at any point where a section was made. Whether this frothy water which thus poured out from the cut surfaces escaped only from minute tubes or had any of it reached the ultimate air-cells and was poured out from the spongy surface itself could not well be determined; it certainly escaped from parts of the cut surface not occupied by air tubes of visible size. The lung thus sodden with water was heavy (though it floated), doughy, pitted on pressure, and was incapable of collapsing. It is not difficult to understand how by such infarction of the tubes air is debarred from reaching the pulmonary cells; indeed, the inability of the lungs to collapse on opening the chest is a proof of the obstruction which the froth occupying the air tubes offers to the transit of air."

---

[1] THE LANCET, Oct. 18th, 1856, p. 440.

The gasping but fruitless attempts at inspiration in drowned animals after removal from the water contrast strongly with the fact that an inspiratory effort after the removal of the plug in simple apnœa is almost invariably successful and followed by recovery, and accords with the different conditions discovered by a post-mortem examination. The conclusion thus arrived at is confirmed by the great length of time that the heart continues to act after submersion. The entire dependence of the early fatal issue in apnœa by drowning upon the patulous condition of the windpipe and its results were strikingly shown in another way by experiment.

Experiment 40.—A strong dog had its windpipe plugged in the usual manner and was then "drowned"—i.e., submerged in water for four minutes; three-quarters of a minute after its release it breathed and in four minutes had recovered fully.

Experiment 41.—A large dog was treated in exactly the same way and with exactly the same result—perfect and immediate recovery after four minutes' submersion.

Experiment 42.—A medium-sized dog was plugged and submerged, just as were the others. The result was just the same—after four minutes perfect recovery.

Here, then, are three cases of recovery after a four-minute apnœa in which the dogs were in every respect under the conditions of drowned animals except that their windpipes were plugged. These experiments form an admirable contrast to the cases of mere drowning without plugging.

Seeing that the entrance of water into the lungs and the formation of foam by its admixture with the air in the bronchial tubes, together with the mucus of their surface, are due to the violent respiratory efforts during the first minute of submersion it appeared that if these efforts could by any means be diminished the result might be somewhat modified. With the view of testing the validity of this opinion dogs were put under the influence of chloroform, and it was found that by simply depriving the animal of the power of breathing without respiratory efforts the periods during which submersion may be continued and recovery follow is at once prolonged. The experiments on the dead body for the production of artificial respiration were conducted on the same lines as ours and the same difficulties were encountered; there was, however, one great and fundamental difference in the mode of procedure—the committee introduced the tube directly into the trachea instead of into the nares as we had done. It is true that by this procedure they avoided the many accidents that might interfere with the amount of air respired, but they lost the great advantage of the knowledge which we had gained in our experiments. Later, however, they were driven to investigate the questions of difficulties which might arise in the pharynx and they entirely confirmed in every detail the force of our assertions that obstructions do occur, and the report goes on to say[4]: "As regards the position of the tongue and its influence in impeding the entrance of air it was found that in the dead body this organ is apt to offer great obstruction to inspiration by falling back into the pharynx and closing the laryngeal aperture."

The committee confirmed, as you see, in every detail the results of our experiments and of those of Dr. Silvester. We were all in accord up to a certain point, but the committee went further and again demonstrated that which we in our experiments had taken for granted—viz., that in drowning we are not dealing with healthy lungs but with lungs, as the chairman repeated, "choked with frothy fluid, and that fluid more or less bloody." These were the words of the chairman, and Dr Edward Smith, so THE LANCET[5] said, adverted to the importance of the quantity of bloody water found in the lungs of the dogs drowned and explained that the water would be introduced from the bronchi into the blood-vessels by endosmosis, and this would cause swelling and bursting of the blood corpuscles after the circulation had been greatly retarded or arrested and would also cause rupture of the capillaries, or the attenuated blood would pass through the walls by exosmosis and thus appear in the bronchi. Further on he said "it had been shown by the report that in a case of phthisis where the lung capacity was greatly reduced the effect of the two methods [the Marshall Hall and the Silvester] was precisely the same. Such would also probably be the case with drowned persons in whom the lungs were full of water, which offered a great obstacle to the introduction of air, and in this condition the committee had not made any experiments. It was in reference to the practical object in the appointment of the committee that the report failed The committee had not proved that any one of their inquiries was applicable to the drowned human subject. The time during which a man could be immersed in water and recover could not be proved by experiments on dogs, and the committee themselves had shown that all their plans for the restoration of drowned dogs had failed. The committee had, in one part of the report, disclaimed any intention to say how far the Silvester method was fitted for the restoration of the drowned; and yet in their recommendations they advise the use of this method almost exclusively, without having in any experiment tried it under these conditions—i.e., on man. The recommendation to place the body prone and allow fluid to run out of the mouth was an old recommendation, but they had *inferred* and not *proved* its value, and that only from experiments on drowned dogs which they could not resuscitate. The experiments on dogs had shown that neither cold nor hot water alone had any value as restorative agents but that the alternative of the two was somewhat useful, but this alternative had not been recommended for man. Hence he (Dr. Smith) regarded this report as but the commencement of the inquiry, a labour which had elicited important facts fitted to be employed in further researches, but as to the great object in view in the appointment of the committee—the scientific determination of the best method for restoring drowned men—he thought that it altogether failed. He urged the importance of the same gentlemen continuing the inquiry and of making experiments under the conditions in which the knowledge must be applied—viz., upon men after immersion. He thought that the results of the present inquiry proved that for the observation of defined facts with known methods of inquiry, or with slight modifications of known methods, the appointment of committees would ensure the work being done at a given time and with authority, provided the names of the observers were appended to each observation; but for the solution of complex questions (as all questions of practice are) committees would fail, since the essence of such an inquiry is the invention of a new method, and new methods can never be devised to order, but only through long-continued thought without the investigator being commonly able to trace the steps which led him to the result. Hence the last series of questions must always be solved as heretofore by individuals, and that not in any particular country, age, or time, but when the happy idea has occurred to an inquirer. Such he believed to be the experience of those who who had been extensively engaged in scientific research. He attached great value to the facts contained in the report."

With these remarks I entirely agree and, from having lived many years at a seaside town and having been favoured with the cordial support of the coastguard officers and my medical colleagues in my own town and others on the east coast I have had several opportunities of observing and treating cases of drowning in the human subject, have tested the value of many questions under discussion, and have brought to a more definite issue the original object of *our* work, of Dr. Silvester's, and of that of the Royal Medical and Chirurgical Society. The more practical part of the subject I propose to deal with in my next lecture.

ON THE AGGLUTINATING PROPERTY OF BLOOD SERUM IN CASES OF PLAGUE.

By D. LOUIS CAIRNS, M.B. Glasg.,
RESIDENT ASSISTANT PHYSICIAN, CITY OF GLASGOW FEVER HOSPITAL, BELVIDERE.

The number of observations which have been made up to this time on the agglutinative power of serum from patients in the course of, or during convalescence from, an attack of bubonic plague is comparatively limited. This is all the more remarkable when one considers the numerous opportunities which have occurred during the last five or six years for such observations. The literature also bearing on the subject is not at present of such extent or completeness as to furnish a basis for inferences of practical value. The earliest reference to this part of the subject which I have been able to find is contained in the report of the German Commission sent to Bombay for the investigation of plague. In their abstracted report, published in the *Deutsche Medicinische Wochenschrift* for 1897, the existence is announced of a definite reaction between the serum of man and animals infected with plague and an emulsion of the specific bacillus. The reaction consists in the precipitation of the bacilli in the form of small distinct floccules when such serum is added to a test tube containing an emulsion of plague bacilli. The report also states that no such precipitation of other organisms by plague serum occurs, the emulsion of these remaining uniformly turbid. The report of the commission, however, makes no mention of the value of the reaction either as a diagnostic or prognostic agent in this disease, and suggests merely that the specificity of the reaction may constitute a reliable method for the identification of the plague bacillus and its differentiation from other organisms closely resembling it. About the same time Paltauf[1] established the existence of the reaction in the blood of animals (guinea-pigs and horses) which had succumbed to inoculations of dead plague cultures. A very slight degree of dilution of the blood, however (from 1 to 5 or even 1 to 1), was employed—a fact which tends to diminish the value of the observations. Considerably greater practical importance attaches to the results obtained by Wyssokowitz and Zabolotny.[2] These authors state that the agglutinative power is not manifest during the earliest and most acute stage of the disease. It first appears in the blood about the seventh day of illness, gradually increases up till the fourth week, and declines after this period. In cases fatal during the first week of illness they found it absent.

A short *résumé* of the results obtained independently by Professor Zabolotny during the epidemic at Bombay in 1897 appeared in the *Deutsche Medicinische Wochenschrift* for the same year,[3] and though no details are given the conclusions to which he has been led substantially agree with those of the last-mentioned observers. In a subsequent paper[4] the method employed for demonstrating the reaction is stated, and from a comparatively large number of single observations the probable curve of the agglutination wave is constructed. I desire here to acknowledge my indebtedness to Professor Zabolotny, to whom, during his stay in Glasgow, I owed several valuable suggestions in the carrying out of my work on this subject. Dr. Leumann of the Bombay Plague Laboratory has also made a considerable number of single observations on the bactericidal and agglutinative properties of plague serum, and while the technique adopted was sufficient for the demonstration of the former property and for rough estimations of the latter, it was evidently quite impossible to obtain reliable comparative data by this method. One or two loopfuls of an agar culture were simply suspended in sterile water and serum was added drop by drop till precipitation of the microbes occurred. No attempt was made to estimate the relative proportions of serum and emulsion, and, as will be shown later, the *sine quâ non* of all agglutinative experiments—viz., a perfectly homogeneous emulsion—cannot be obtained by this method. A short paper by Dr. E. Klein[5] completes the list of those which I have hitherto been able to consult. In it he mentions the difficulty and emphasises the importance of obtaining a perfectly homogeneous distribution of the bacilli in the emulsion to be used. (This is referred to in a later part of the present paper.) The extensive report of the Austrian Commission contains, so far as I am aware, no reference to this aspect of the subject, and the comparatively short paragraph devoted to it in the exhaustive work of the late Dr. Müller of Vienna[6] is indicative of the necessity for extending our observations on the subject.

The recent outbreak of bubonic plague in Glasgow provided an opportunity of furnishing an additional contribution on the character and significance of the agglutinative phenomenon in this disease. It has been my desire to gauge as accurately as possible the degree of completeness of the reaction at several stages of the disease in the same individual, so that a basis for the estimation of its value at any particular period may be established. The following record contains particulars of 24 cases examined with this specially in view, and considerably over 300 agglutination tests have been performed to furnish the strictly comparable data. The fact that the entire series of observations was made by myself is mentioned only to indicate that the standard of comparison by naked-eye examination of all the reactions has been practically uniform throughout.

Unfortunately, many of the earlier agglutinative experiments performed with plague serum in this research were rendered of comparatively little value owing to the fact that a mode of procedure was adopted similar in all respects to that now in common use for obtaining the agglutinative reaction in enteric fever. The method adopted for the latter purpose becomes inapplicable to plague because the specific bacillus, unlike that of enteric fever, does not produce in peptone bouillon a homogeneous turbidity during growth, but tends to cohere either in the form of strands of varying lengths ("stalactites") or as minute floccules which are aggregated mainly on the sides and bottom of the tube, and to a lesser extent occur throughout the fluid medium. It was found impossible by means of prolonged agitation of such a culture to produce a homogeneous suspension of the bacilli. After such treatment, the micro-organisms were found to settle at the bottom of the tube in the form of a loose powdery deposit, and on microscopical examination clumps of minute size were found throughout the supernatant fluid. The most important condition for the performance of a trustworthy series of experiments in agglutination or sedimentation—viz., an absolutely homogeneous emulsion of the young organism—is therefore, in the case of bacillus pestis, unobtainable with peptone bouillon. The cohesion of the bacilli during growth in bouillon (possibly related to the development of an adhesive agent connected with the capsules of the organisms by which zooglœa-like masses are formed) is also exhibited during growth on the surface of agar-agar. If the surface of such a culture of 24 hours' incubator growth be touched with a platinum loop its slimy consistence becomes at once apparent, and while the needle is being removed a fine gelatinous thread is drawn out from the growth on the tip of the wire. This becomes a more marked feature in slightly older cultures. The difficulty in obtaining such an emulsion of plague bacilli was one which entailed a considerable amount of experimental work. It was ultimately found that a homogeneous emulsion could be obtained in sterile 0 75 per cent salt solution. It is noteworthy that Dr. Klein, whose paper on the subject has recently appeared, has solved the same difficulty after trial of various expedients in an almost precisely similar manner. This method yields a perfectly homogeneous and workable emulsion which remains practically unchanged for 24 hours, showing no signs of clarification in the upper portion of the fluid and no great tendency to the deposition of micro-organisms at the foot of the tube. A drop of this fluid examined under the microscope shows the bacilli perfectly free and isolated from each other, and, if carefully prepared, ought to be entirely free from any clump-formations.

The following was found the most suitable method of preparing the emulsion, which, in view of the necessity of obtaining reliable comparative results in each case, was required in considerable quantities. Several sloped agar tubes, which had been inoculated from a 24 hours' culture of bacillus pestis, were incubated for from 24 to 36 hours. Cultures which showed the presence of involution forms in considerable numbers, or which had been incubated for longer periods than 48 hours, were not (and should not be) used for this purpose. The tubes were then filled with sufficient 0 75 per cent. sterilised salt solution to cover the solid medium. The growth was then as far as possible transferred to the salt solution. This was carried out most efficiently and without tearing the surface of the agar in the process by rubbing the growth with the rounded extremity of a sterile Pasteur pipette the end of which had been previously curved in the form of a shepherd's crook. The various emulsions so prepared were then decanted into a large sterilised test tube which was set aside for a short time to allow any cohering masses which might be present to settle. If the growth had been very luxuriant a more sensitive emulsion was usually obtained by diluting still further with salt solution. The exact degree of dilution with salt solution is undoubtedly a matter of some importance and can only be determined after considerable experience in agglutinative work. As a matter of frequent observation it may be stated that too concentrated emulsions are agglutinated very slowly and often very imperfectly. In the following series of observations the emulsions were all prepared from the same stock cultures, incubated for approximately the same length of time, and as far as possible grown under exactly similar conditions. It need hardly be added that the cultures used responded to all the recognised tests for the complete identification of the bacillus pestis. Inoculation of animals with these cultures reproduced the disease with its characteristic lesions and after death the specific bacillus was recovered from the blood or organs.

In performing experiments on agglutination two chief methods are recognised: (1) the microscopical and (2) the macroscopical or sedimentation method. The result of a considerable number of comparative trials of both methods indicated that on the whole the latter yielded more reliable data. By means of the microscopical method, however, pronounced and in every way characteristic reactions can be demonstrated in much higher dilutions than by the latter technique, but data so obtained are frequently vitiated by the occurrence at times of puzzling and apparently unaccountable pseudo-reactions. Consequently, though the potency of a given serum was estimated in most instances by both methods, only the sedimentation test was adopted throughout this series of observations as the standard for performing comparative quantitative estimations, and no serum was regarded as yielding a positive result which failed to give a satisfactory reaction by this method. The reactions were carried out with serum separated directly from blood collected in sterilised Pasteur pipettes, care being taken in every possible way to avoid its contamination. By so doing the possible introduction of a fallacious factor in the means used for obtaining serum by a blister was avoided. The amount of time absorbed in the careful separation of serum directly from blood necessarily limited the number of observations made. It may be stated, however, that no visible difference either in the degree of the reaction or in the time within which it made its appearance could be detected in several instances where serum separated from blood and that obtained from a blister were used from the same case and at the same date for purposes of comparison.

Before undertaking a consecutive series of observations it is well to prepare beforehand all necessary apparatus so that no delay may take place at any stage which might interfere with or vitiate the comparative value of individual reactions. Accordingly it was found advisable to have in readiness a supply of ordinary Pasteur pipettes about 30 centimetres in length and an equal number of a slightly modified pattern. The latter were provided with a capillary portion of a length equal to the distance between the open extremity of the ordinary Pasteur pipette and the commencement of its capillary portion; in addition, a constriction or neck was fashioned on the upper end of the tube about three quarters of an inch below the level of the cotton plug. Blood is most conveniently obtained from puncture of a finger, the skin being first rendered sterile according to recognised methods. All traces of antiseptics having been removed by a final washing with spirit the finger is carefully dried with aseptic gauze and the pulp punctured with a sterilised bayonet-pointed needle. The drop of blood which exudes is immediately aspirated into a sterilised Pasteur pipette the sealed extremity being first passed through a flame and then snapped across at a suitable level by means of sterilised forceps. By "massaging" the finger from above downwards and aspirating each drop as soon as it appears, a quantity sufficient not only for the immediate performance of the reaction, but also for purposes of comparison subsequently, can usually be obtained. In this way from half to one cubic centimetre of blood may be furnished by a single successful puncture. During aspiration care should be taken to avoid the introduction of any air bubbles, as these interfere to some extent with the formation of a firm coagulum and a resulting clear serum. The fine extremity of the tube is then sealed by drawing it out in a spirit flame, unnecessary heating of the contents being carefully avoided. The pipette is kept in an upright position and set aside in a cool place for several hours pending the separation of the serum. If no air has been introduced a firm coagulum usually forms at once and may be seen floating in the centre of the tube surrounded by a perfectly clear serum. If, however, during the process of aspiration the blood has been more or less churned up with air, then it is better to set the tube aside for from 12 to 18 hours. The resulting serum in this case is apt to contain a considerable number of red corpuscles, and though these in no way interfere with the satisfactory performance of the reaction a clearer serum is obtained if time be allowed for the sedimentation of the red corpuscles. The separation of the serum from the coagulum is effected by means of the modified pipettes. The cotton-wool plug being removed from the tube containing the blood, the sealed extremity of a modified pipette is first snapped across with sterilised forceps, the capillary portion introduced into the former and carried down to the conical narrowing of the tube. The clear serum is then aspirated into the second tube and the capillary portion sealed at a suitable level by drawing out in a flame. Before doing so, however, the precaution should be observed of aspirating all the fluid into the body of the tube so as to avoid any undue heating of the serum. If the preservation of the serum for any length of time is desired the pipette may easily be converted into a hermetically sealed capsule by drawing out the constricted portion in a Bunsen flame. On account of the difficulty of preparing two emulsions of exactly the same density it is always better to subject at one time as large a number of sera as possible to the influence of a single emulsion. For the same reason when performing quantitative estimations it is absolutely necessary to compare the agglutinating power of the serum under observation with that obtained at a previous date, the potency of which has already been ascertained by repeated experiment. Only by so doing is it possible to establish an arbitrary standard and so gain an accurate conception as to the quantitative value of individual reactions. When results materially disagreed with previous observations the data so obtained were disregarded and the series of reactions again observed with a fresh emulsion.

The reaction is conveniently performed in test tubes about nine centimetres in length prepared from ordinary soft-glass tubing of about 0·7 centimetre internal diameter. These are thoroughly cleansed and dried, the open extremity being closed with a plug of cotton-wool. After sterilisation at a temperature of 160°C. for an hour they are ready for use. In all cases the reaction was carried out in at least three dilutions, and in many instances with sera possessing a high degree of potency in five dilutions. The proportions adopted throughout have been: 1 in 10, 1 in 25, 1 in 50, 1 in 75, and 1 in 100 In no case has an undoubted reaction been obtained in a dilution higher than 1 in 75, and reactions lower than 1 in 10 have not been recorded, as the necessarily large relative dilution of serum with the emulsion in such preparations yields a practically clear fluid in which the determination by the naked eye of any agglutination becomes a matter of extreme difficulty.

The reaction is conveniently performed as follows. A long Pasteur pipette is taken and its capillary portion snapped across at a level corresponding in diameter with that of the capillary portion of the pipette containing the serum under examination. It is thus ensured that drops issuing from the orifices of these two pipettes will have as nearly as possible the same volume, and in this way any required dilution of serum with emulsion can be readily performed. The Pasteur pipette, the wider portion of which is guarded by two cotton-wool stoppers to prevent possible accidents during inspiration, is filled with the bacillary emulsion. A drop of serum having been introduced into each of a series of sedimentation tubes the emulsion of bacilli is added to each drop by drop to produce the requisite degree of dilution. The serum and emulsion are thoroughly mixed and the cotton-wool stopper is replaced in the sedimentation tube. It is convenient to place vertically in a small deep box the requisite number (from three to five) of sedimentation tubes for each serum under investigation. This obviates the necessity of labeling each tube and at the same time prevents confusion. The degree of dilution can then be readily inferred from the volume of fluid in each tube. When completed the whole series is set aside in a cool chamber for from 18 to 24 hours. As control experiments in each series two or more tubes containing (1) a quantity of the bacillary emulsion and (2) emulsion + normal serum in corresponding dilutions were employed If at the end of 24 hours any degree of sedimentation had taken place in these latter the data obtained from this series were not recorded. Under ordinary circumstances, however, no changes were observed in the control tubes, whilst in the case of those containing serum from a convalescent plague patient a remarkable alteration became apparent after a variable interval of time and according to the potency of the serum. The emulsion was seen to clarify from above downwards till practically the entire column of fluid became absolutely clear. This change was due to the precipitation of bacilli to the lower part of the tube, where they form a loose flocculent deposit. On examining this bacillary deposit under the microscope it was observed that the capsules of the organisms had become indistinct. In the case of powerfully agglutinative sera the process may be observed to commence after one or two hours, but as a rule the reaction is rarely completed till 24 hours have elapsed. Consequently the latter has been adopted as the uniform time limit throughout this series of investigations. In high dilutions or when dealing with sera of feeble agglutinative power the reaction, as might be expected, is less complete. Comparison with the control tubes, however, show that while a certain degree of clarification and precipitation has occurred at the end of 24 hours the process has stopped short of completion, leaving a slightly opalescent appearance in the tube. In the following tables such reactions are indicated by the sign +f (feeble), as the precipitated microbes showed the same microscopical changes as in complete reactions. A complete reaction is indicated by the positive sign + whilst the negative sign – indicates that no reaction has taken place. In the case of powerfully agglutinative sera, when clarification of the emulsion occurs soon after performing the dilution (from one to two hours), the double sign + + has been used.

The following tables represent in a condensed form the result of over 300 separate agglutination tests of the serum taken at different stages of the illness from 25 plague patients. The reports of many of these cases have already appeared in this journal, and as the remaining cases of interest will be published shortly detailed clinical histories have been purposely omitted in this paper. It has been deemed advisable, however, to add short clinical *résumés* of those mild cases in which bacteriological confirmation of the diagnosis was not available. The cases examined were all of the bubonic type, and of these nine received at one time or other varying doses, either subcutaneously or intravenously, of Yersin's anti-plague serum. The agglutinative reactions in these cases, however, were probably not modified to any considerable extent by the previous administration of the serum for curative purposes. In support of this it may be here remarked that the blood serum of individuals who had received one or more prophylactic doses of this serum showed no evidence whatever of agglutinating power. It is therefore highly improbable that the data so obtained have been vitiated in the slightest degree, as even the remedy itself when mixed with a highly sensitive emulsion fails to produce any visible change after the lapse of 24 hours. With the view of ascertaining the possible effect of a mixed infection on the agglutinative reaction I undertook a complete bacteriological examination of most of the organs in fatal cases of plague. These results are appended in Table I. Reference to the cases in Table II. shows that the presence of micro-organisms other than the bacillus pestis in the blood or organs of a patient dead from bubonic plague does not prevent the development of the specific reaction.

For purposes of classification the cases have been arranged in the following groups.

Table II. shows the results obtained from six fatal cases, in all of which the presence of the bacillus pestis was verified by reproducing the disease with its characteristic lesions in animals. Cultures of the specific bacillus were obtained during life, either from the bubo or blood of the patient, or post mortem from the various organs. These were either injected subcutaneously or a small quantity of an agar growth placed in the nasal cavity of an animal and the bacillus again recovered from the tissues after its death. In this group of cases the reaction was also demonstrated with other body fluids—viz., pleural effusion, pericardial effusion, peritoneal fluid, and bile. With respect to the first three of these it will be observed that, in comparison with blood serum a relatively high degree of agglutination has been noted in the only three cases in which it was possible to perform the test with these morbid exudations.

Table III. comprises those severe cases terminating in recovery, from all of which the bacillus pestis was obtained by puncturing the bubo. A sterilised hypodermic syringe was inserted into the glandular swelling and from the serous fluid withdrawn the specific organism was demonstrated on direct microscopical examination of smear preparations. Culturally the organism isolated from each case responded to all the recognised tests for the identification of Yersin's bacillus, and, as in the first group of cases, was further verified by the biological test. In the case of Mrs. M. it was thought unnecessary to perform a bacteriological examination of the bubo, as the patient's daughter (Mrs. M.), granddaughter (baby M.), and son (Robert M., see Table II.), all died from bubonic plague.

Table IV. comprises those comparatively mild cases of plague with characteristic bubo. From the first three of these the specific organism was isolated and identified as above, but only in the case of Mrs. G. was the proof completed by animal inoculation. In the last three cases (James C., Rosina M., and Dennis T.) it was found impossible to cultivate the organism either from the juice obtained by puncture of the glands, or at a later stage when the bubo

had broken down from the sero-purulent discharges. The failure to obtain the bacillus in these cases was no doubt due to the comparatively late stage of the illness at which the patients first came under observation. As the disease ran an exactly similar course, however, to those from which the specific organism had been recovered, and as in each instance the serum possessed marked agglutinative power, there appears to be every possible reason to regard them as undoubted though mild cases of plague. The following synopsis of the clinical features of these cases reveals their character sufficiently.

Dennis T., aged five years. This patient was admitted on the eighth day of illness with a glandular swelling in the right inguinal region which presented the characteristic appearance of a plague bubo in the stage of resolution. The enlargement was limited to the vertical set of glands, the skin over and around it being inflamed and exceedingly tender. The patient, though not acutely ill, was drowsy and showed a lack of interest in his surroundings. Examination of the heart and lungs revealed nothing noteworthy. The admission temperature of 100 4° F. was never exceeded and a few days later the patient seemed quite well, though the bubo, while less tender, showed no signs of resolution. On the sixteenth day of illness spontaneous rupture of the bubo took place, convalescence thereafter being rapid and complete. Cultures from the bubo, made as above described, proved sterile, though smear preparations showed the presence of numerous degenerated bacilli. No doubt, however, can be entertained as to the nature of this patient's illness both on account of the association and the clinical appearances. The patient's grandfather (James B., Table II.) died from plague, and his mother (Mrs. T., Table III.) passed through a very severe attack of this disease. The identity of the isolated organisms in both these latter cases was verified by animal experimentation.

James C., aged 24 years. This patient was admitted to hospital on August 30th, 1900. He slept for a single night on August 13th in a room on the same landing as several of the other plague patients, though his usual place of residence was at a considerable distance from the plague infected area. On August 16th he was seized with an illness, evidently of considerable severity, associated with headache, sickness and vomiting, and pain in the left inguinal region. The report received from the medical attendant, Dr. G., is as follows. On August 17th the temperature was 103° F. and the pulse 102. There was severe headache with vomiting. The patient complained of pain in the left inguinal region where there were some redness and swelling. On the 21st the temperature was 102 6°, the pulse 98, while the swelling had increased in size and was still painful. On the 24th the temperature was 100 and the pulse 90. The swelling was sausage-shaped and lay along the upper border of Poupart's ligament; it was fairly hard and pitted on pressure. On admission the patient was evidently convalescent, no sign of illness being present. The temperature was normal. On examination of the left groin, however, a swelling rather larger than a pigeon's egg was discovered immediately above Poupart's ligament and evidently involving the horizontal set of glands. The overlying skin was inflamed and slightly œdematous and fluctuation could be easily obtained A hypodermic needle inserted into the glandular swelling withdrew a quantity of dark grumous fluid which, on microscopical examination, showed the presence of numerous degenerated bacilli; and though a considerable number of agar tubes were inoculated on two separate occasions no growth whatever could be obtained. Convalescence was uninterrupted, the bubo disappearing by absorption.

Rosina M. was admitted from the plague-infected area in her third week of illness. At this date all clamant symptoms had subsided, but examination of the inguinal region on each side showed the presence of a bilateral bubonic condition involving the group of glands situated immediately above Poupart's ligament. Each bubo was about the size of a large walnut, that on the left side being comparatively firm and painless, whilst in the other fluctuation could be easily detected. On both sides the overlying skin was inflamed and adherent to the glands beneath. The history of the illness obtained from various sources showed that the onset was sudden and acute and was characterised by high fever (temperature 104° F.), accompanied by rigors and delirium; headache, sickness, and vomiting were also present and continued for some time after the appearance of the buboes which were discovered by the patient herself on the third day of illness. These were apparently exceedingly painful at this stage. They rapidly increased in size during the succeeding two or three days, after which the tenderness slowly subsided. The bubo in right groin ruptured spontaneously in the fourth week of illness, discharging a sero-purulent fluid for about 10 days, whilst that on the left side underwent resolution without rupture. Both buboes were explored with a hypodermic needle as in previous cases and culture tubes inoculated with the aspirated fluid remained sterile. At a later date the subcutaneous injection of a mouse with the discharges from the right bubo was unattended by any serious disturbance in the animal's health.

The remaining cases grouped in Table V. may be regarded, both from the etiological and clinical standpoint, as fairly typical examples of *pestis ambulans*. In all the illness was apparently so slight that, apart from a definite history of contact with infected persons and in the absence of a bacteriological examination, it would have been quite impossible to pronounce upon the exact nature of the glandular affection. The general course and symptomatology of such cases has already been described in a previous article and it will therefore be sufficient here to indicate briefly the salient points of each case.

Of these the most interesting is the case of a ward-maid in one of the pavilions set apart for the isolation and treatment of plague patients. Ten days prior to the commencement of her illness she had received a prophylactic injection of 10 cubic centimetres of Yersin's serum. The illness, however, was of a comparatively trifling nature, the patient only complaining of a moderate degree of indisposition for about three days. Bacteriological examination, however, demonstrated the presence of the plague bacillus in an exceedingly small cervical bubo. The serum taken during the third week of illness agglutinated an emulsion of plague bacilli in a dilution of 1 in 25 though the constitutional disturbance was so slight that the temperature and pulse throughout the illness never rose above normal.

Agnes R., aged three and a half years. This patient was a "contact" from the Molloy wake—one of the first discovered foci of infection. The illness, of sudden onset, was accompanied by headache, sickness, and vomiting, and pain in the left axilla Examination of this region showed the presence of a small bubo, but an exploratory puncture failed to withdraw any lymphatic gland fluid. The temperature rose to 101° F. on the first day of illness and subsided to normal two days later. Convalescence was rapid and complete.

The cases of Archibald D. and William M. are fully reported in THE LANCET of Sept. 22nd and Sept. 15th, 1900.

In the remaining three cases the sudden appearance of bubo (axillary in one case, cervical in the others) was associated with symptoms of fairly acute onset, similar in all respects to those already described. In these, however, a bacteriological examination was not undertaken, but the peculiar nature of the illness, taken in conjunction with a very definite history of exposure to infection, seems sufficient to warrant these cases also being regarded as examples of the mildest variety of this disease. It may here be added that the serum of patients suffering from various forms of specific infectious disease and taken at various stages of their illness was examined in different degrees of dilution with an emulsion of bacillus pestis. In no case was any reaction observed. The diagnostic value of its appearance, therefore, in cases associated with slight glandular enlargement is to this extent enhanced.

The following deductions appear fully warranted from an examination of the accompanying tables. 1. During the early days of the disease the reaction is not manifested and consequently in rapidly fatal cases is probably never obtained. 2. Agglutinating properties first appear in the blood towards the close of the first week of illness (dilution of 1 in 10). These gradually increase in intensity up to the sixth week of illness and are sometimes maintained at a high level as late as the eighth week. After this date, however, in the majority of cases a gradual decline in the agglutinative power of the serum becomes apparent. The rates of increase and decrease of the reaction, generally speaking, are approximately equal; occasionally, however, the reaction wanes and disappears in a shorter period than that occupied between its appearance and point of maximum intensity. 3. In very severe cases ultimately proving fatal the reaction though present never reaches a high degree of intensity. In cases

of almost equal severity, however, in which an early and rapid convalescence followed, the reaction was of a more marked character. 4. In the mildest forms of plague a high degree of agglutinating power is probably never attained and in some it appears to be absent. Stricker, in fact, states that the reaction never appears in this class of case, but this is undoubtedly too sweeping an assertion, as an undoubted and characteristic reaction in a dilution of 1 in 25 was obtained in two such cases. 5. The reaction, as a rule, is most marked in those severe cases characterised by an early and favourable crisis, and in such cases it disappears very slowly, having been shown to be present as late as the fifth month after the primary illness.

Other methods.—The technique just described is, however, perhaps unnecessarily complicated, as in order to avoid any possible source of fallacy a number of precautions were adopted which later experience showed to be superfluous. The initial difficulty—the preparation of a perfectly homogeneous bacillary emulsion—having been overcome, an almost precisely similar technique to that employed in the ordinary Widal reaction may be adopted. As already stated, the dilution of serum with emulsion can be carried to a much higher degree and the time-limit considerably shortened when the microscopical method is employed. By this means reactions in which the bacilli are completely agglutinated in from five to 10 minutes are fairly common with potent sera in dilutions of 1 in 10 and 1 in 25. If, however, the dilution be carried further it is absolutely necessary for trustworthy results to observe the reaction in hanging-drop preparations. In this way well-marked reactions have been obtained in dilutions of 1 in 200 with a time limit of two hours, though preparations made between an ordinary slide and cover-glass showed no evidence whatever of any agglutinative process. The time-limit may be safely extended to 24 hours if the edge of the cover-glass be sealed with vaseline. By this method a reaction can often be demonstrated with sera of feeble agglutinative power or with potent sera which have been highly diluted. As a control experiment preparations of (1) emulsion and (2) emulsion plus normal serum have been kept for over a week without any signs of undoubted agglutination supervening. Numerous observations of plague sera in progressively increasing dilutions have been made and the time-limit in each case has been carefully noted. The data so obtained may be compared with those got by the sedimentation test at corresponding periods. To illustrate this the results obtained by this method from two severe cases of plague terminating in recovery (Table III.) are exhibited in the accompanying table (Table VI.).

Like results may be obtained with similarly prepared emulsions of dead plague bacilli, but in this case the reaction is not so reliable, as the dead organisms are not agglutinated so readily. When working with dead cultures, however, the microscopical is to be preferred to the sedimentation method, since it yields more trustworthy results even in higher degrees of dilution. In the absence of facilities for obtaining a homogeneous emulsion of living or dead bacilli Haffkine's prophylactic (which contains the latter) may be used to dilute a suspected plague serum. No satisfactory reaction, however, has been got by this means in a higher dilution than 1 in 25, and the sedimentation method is alone applicable owing to Haffkine's prophylactic being a bouillon culture. This last method can only be regarded as a makeshift.

Concluding remarks.—From the point of view of hygienic administration the very mild cases of plague are of the utmost importance. The analogy presented by all other infectious diseases indicates that such cases must be regarded as of equal importance with the more severe forms in the possible dissemination of the disease and constitute therefore a grave source of danger to the community. It is well known that epidemics of measles, scarlet fever, and diphtheria are frequently preceded by a type of the disease so mild that many cases are allowed to remain untreated, and it is interesting to note that several of the outbreaks of plague in the East have been heralded by the mildest possible form of the disease. Moreover, the difficulties attendant on a successful exploratory puncture of a small deep-set gland are sufficiently obvious and any other means of arriving at a definite conclusion as to the nature of an obscure glandular swelling is certainly entitled to the most careful consideration.

In the severer forms of the disease the possibilities of a serum diagnosis are much greater. It has already been shown that during the early stages of the illness the agglutinative properties of the blood are but freely developed and that unless a careful technique be adopted for its demonstration the reaction is liable to be missed altogether. After the second week of illness, however, and particularly in those cases where the bubo undergoes resolution, the chances of obtaining the bacillus by puncture of the gland diminish rapidly during convalescence. This fact is well illustrated by the last three cases in Table IV., in which attempts to cultivate the organism by this method at the end of the first, second, and third weeks of illness respectively completely failed, though numerous degenerated bacillary forms were seen in smear preparations. Indeed, in the case of Mrs. M. (Table III) culture tubes inoculated on the eighth day of illness with fluid obtained from puncture of the bubo proved sterile, though two days previously an actively growing pure culture had been obtained. On the other hand, the agglutinative power of the serum, insignificant at the commencement of the illness, progressively increases up to *the sixth or seventh week of the disease, by which time a comparatively high degree of potency has been attained*, especially in the severer forms of the disease which recover. Thereafter it begins to decline, but, as already shown, may be present in well-marked cases four or five months after the primary illness It is therefore during and subsequently to the stage of convalescence, when the possibility of a bacteriological diagnosis is more or less remote, that the diagnostic value of the reaction becomes most apparent. In all cases, moreover, associated with the presence of glandular enlargements of dubious nature, the occurrence of which from time to time during the progress of an epidemic of plague may present a diagnostic problem of perplexing character, the application of this reaction cannot fail to prove of signal service.

Glasgow.

SUGAR-FREE MILK AS A FOOD FOR DIABETICS.

BY ROBERT HUTCHISON, M.D. EDIN., M.R C P. LOND.,
ASSISTANT PHYSICIAN TO THE LONDON HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THE difficulty often presents itself in practice of providing a patient suffering from diabetes with a diet which, while wholly free from carbohydrate, can yet be taken without repugnance for a prolonged period of time. The essential point of such a diet is that its nutritive constituents must consist only of proteid and fat. As far as possible most of the energy which it yields must be derived from fat, for there are certain risks and disadvantages incidental to an excessive consumption of proteid. But, unfortunately, it is often difficult to persuade a diabetic to eat enough fat. Bacon he can usually manage and a certain amount of fat meat and fish, and perhaps even some salad oil, but the necessary exclusion from the diet of bread and potatoes renders it difficult *to administer even moderately large* quantities of that most easily digested of fats—butter. A little can be got down on some variety of starchless bread or in the form of sauce with fish or mixed with green vegetables, but in many cases the most that can be managed in these ways does not exceed three or four ounces daily

Now, in milk we have fat and proteid in a form in which they may be easily taken and are readily digested, while the special form of proteid present in milk (casein) has the additional advantage that it is not capable, as most proteids are, of yielding sugar in the body. Unfortunately, however, milk itself contains a carbohydrate in *considerable amount* (4 per cent), and though it may be true that in *some* cases milk sugar is better borne than most other forms of carbohydrate, yet it must be remembered that, as experiment has shown, lactose is not directly assimilated in diabetes Experience shows, too, I think, that in the majority of such patients the addition of milk to an otherwise strict diet increases the amount of sugar in the urine and coincidently with that aggravates the thirst and the other symptoms which are due *to the presence of an excess of* sugar in the blood. It is not surprising, therefore, that attempts have from time to time been made to get rid of the sugar in milk whilst retaining its other ingredients. In standard works on diabetes a description of several such sugar free milks will be found, but hitherto they have not found very general acceptance, partly, perhaps, because they are troublesome to make at home and it has not as yet been possible to buy them ready-made. I have described elsewhere[1] a sugar-free milk prepared for me by Mr. Morris, chief dispenser to the London Hospital, which has now been brought to a very high degree of perfection and which can be obtained for use at home in a sterilised form [2] This milk contains all the original casein and salts along with a certain additional proportion of fat. It is practically sugar-free and can hardly be distinguished from a rather rich specimen of ordinary milk. It can be readily administered either plain or with some effervescing water or it can be added to tea, coffee, or cocoa. It has also the advantage that it can be made into boiled or even baked custards with eggs, thus rendering it possible to add a nourishing and harmless "sweet" course to the diabetic patient's dinner. Assuming that it contains about 3 per cent. of proteid and 5 per cent. of fat and that three pints are taken in one form or another in the course of a day, the total energy yielded *will be about 990 calories or almost one-third of the total amount required, while the amount of fat which the* patient gets is equivalent to fully three ounces of butter. I have had this form of milk in constant use in hospital practice for more than a year and have found it of the greatest service It is specially useful in those cases in which it is desirable to observe as strict a diet as possible, but even in those instances in which it is decided that a limited amount of carbohydrate can be taken with advantage it will be found best to substitute sugar-free milk for ordinary milk and to give the allowable quantity of carbohydrate in the form of potatoes and bread. *This plan is not* only more satisfactory to the patient, but it has also the advantage of enabling one to administer larger quantities of butter. The scheme of a strict diet which includes the use of this milk would be something as follows:—

Breakfast—Bacon, eggs scrambled with butter; fish and butter sauce or some form of cold meat; toasted protene bread with plenty of butter, and café-au lait made with sugar-free milk and sweetened with saccharin if desired

Dinner—Soup (without vegetables or other carbohydrate containing matter), fish (preferably one of the fatter sorts); meat with green vegetables and melted butter, custard of eggs and sugar-free milk, and cheese with protene bread and watercress. Beverage: whisky and water or any dry natural wine.

Supper—A cup of well made beef tea; eggs in some form—e.g., as an omelette with as much butter as possible; fish or cold meat, and cheese with protene bread and butter and a salad with plenty of salad oil Beverage a glass of sugar-free milk.

The rest of the milk, sufficient to make the total daily allowance *up to three pints*, should be taken as a beverage between the chief meals

The above diet is, of course, merely an outline which can be modified to suit the taste of individual patients, but it will be found to answer very well in practice and is practically free from carbohydrates. I have recently had a patient on it who was passing on an ordinary diet more than 300 grammes of sugar per day and who on the above diet had an excretion of only about 25 grammes and gained weight rapidly. The attainment of this result was greatly facilitated by the use of sugar-free milk, and my object in writing this short article is to try to make the merits of the latter *more* widely known among the profession.

London Hospital

THE VALUE OF ANTITOXIN IN THE PREVENTION OF DIPHTHERIA.

BY A. E PORTER, M D., D P.H CANTAB.

IN the belief that the prophylactic administration of antitoxin is not so largely used in this country to prevent the extension of diphtheria among inmates of infected houses and institutions as its success seems to warrant, I hope that the following account of cases in which it has been employed and which have come under my notice as assistant to the medical officer of health of the County of Essex and of the combined rural districts of Chelmsford and Maldon may be of interest not only to medical officers of health, but also to those members of the profession who are engaged in general practice.

---

[1] Food and the Principles of Dietetics. London: Edward Arnold. Second edition, 1901, p 474

[2] *Prepared by Messrs Clay, Paget, and Co., 23, Ebury-street, S W.*

During the past 12 months diphtheria of a virulent type has been extremely prevalent throughout the greater part of Essex, and the Chelmsford and Maldon rural districts have suffered severely in this respect. With a view of attempting to check the epidemic the councils of the two districts have lately agreed to pay to medical practitioners a small sum for each prophylactic injection of antitoxin given with the sanction of the medical officer of health on the occurrence of a case of diphtheria in a household. Up to the present this practice has been adopted in 24 families, with the gratifying result that, with one possible exception, not a single person so injected has subsequently developed diphtheria, notwithstanding the fact that two-thirds of the cases were treated at home. In eight instances the injection was refused, and amongst these there were three subsequent cases of diphtheria. One of the houses (No 3) was a home for orphan children; all the remainder, with two exceptions, belonged to members of the labouring classes; many of them contained but two sleeping-rooms, and these frequently communicated with one another. Wherever there was any doubt as to the nature of the case a bacteriological examination was made to confirm the diagnosis. Of the 136 persons thus protected 60 were adults of 20 years of age and upwards. The remainder were children chiefly at about the school age, and swabs from the throats of many gave almost pure cultures of the diphtheria bacillus on blood serum.

The following is a tabular list of the families to whom prophylactic injections were administered :—

TABLE I.

Family.	Number of cases notified before injection was given.	Number of members in family to whom prophylactic injections were given.	Number of persons thus injected who subsequently developed diphtheria.	Number of persons to whom no injection was given.	Persons not injected who subsequently developed diphtheria.	Remarks.

In No. 19 the mother of a child suffering from diphtheria received a prophylactic injection and in a few days suffered from sore-throat. As she was nursing the case, which was a severe one and terminated fatally in a few days, it is probable that she too caught the infection. The attack was, however, so mild that she was scarcely prevented from attending to her household duties, and she escaped notification. There was, therefore, only one failure, and that a doubtful one, out of 136 cases in which prophylactic injections were given.

For purposes of comparison I have drawn up a second table showing the number of secondary cases occurring in another series of 24 families, taken consecutively from our notification records before the prophylactic injections came into force. The number of individuals in the families is approximately the same, as is also the proportion of adults, of whom there were 53. It will be seen that in one-third of the houses secondary cases occurred and that one-sixth of the inmates contracted the infection in the absence of the prophylactic injections, in spite of the fact that a larger number of the primary cases were promptly removed to the hospital. This series of families has in no way been specially selected, and the proportion of houses in which secondary cases have occurred has practically obtained throughout the present epidemic.

TABLE II.

No doubt similar instances of the efficacy of this mode of prevention could be indefinitely multiplied. A striking example is mentioned by Mr. J. Damer Priest, medical officer of health of the Waltham Holy Cross Urban District Council, in his annual report for 1900. Three cases of diphtheria occurred at short intervals in a convalescent home for children situated in his district. The remaining 35 children were injected and there were no further cases.

In America this method of treatment is adopted on a large scale. In the city of New York, between Jan. 1st, 1895, and Jan. 1st, 1900, no less than 6806 persons who had been exposed to infection were given prophylactic doses by the officers of the Board of Health; of these 19, or less than 0·3 per cent., afterwards contracted diphtheria, and only one of them, who was suffering from a simultaneous attack of scarlet fever, died.

The success which attended the methods adopted in arresting the recent outbreak of diphtheria in the borough of Cambridge is still fresh in our memory, and the report by the medical officer of health (Dr. Bushell Anningson) is well worthy of study by all those who are interested in preventive medicine. Unfortunately, it cannot be claimed that an injection of antitoxin will prevent an attack of diphtheria with absolute certainty, but it will undoubtedly do so in a large proportion of instances, and, if diphtheria should occur, the attack will in all probability be a mild one. As to what constitutes an efficient dose authorities differ. By some 300 units are considered sufficient, whilst others inject 800 to 1000 units. Our practice in the Chelmsford and Maldon rural districts has been to give 500 units, and so far with satisfactory results. Such a dose can usually be obtained in a bulk of about 20 minims and a hypodermic syringe may therefore be used for the purpose. With 500 units it is rare to experience any serious after-effects if the injection be made in the loin or between the scapulæ. With larger doses the rash and the joint pains occasionally associated with the use of antitoxin are sometimes met with, their occurrence being due to the particular batch of serum used and possibly to individual idiosyncrasy. As a rule there is a slight rise of temperature and occasionally a feeling of malaise and nausea within 24 hours of the operation, often followed by some irritation round the seat of injection. The first three symptoms quickly pass off, the last may persist for a few days. If, however, the serum be injected into the arm sequelæ are frequent and consist chiefly of inflammation and œdema, together with stiffness of the joints and intense irritation.

It is important to bear in mind that where antitoxin is used as a prophylactic in persons who are actually harbouring the diphtheria bacillus, although the clinical symptoms may be averted, the throats are none the less infective—at all events the bacilli may, in my experience, remain for weeks. Hence such persons are still liable to become foci of infection and should be prevented from spreading the disease until sufficient time has elapsed to eliminate the danger or until they are shown by bacteriological methods to be free from infection.

As a result of my experience detailed above I believe that we possess in antitoxin a valuable means of preventing the onset of diphtheria in persons who have been exposed to infection, and that it is of especial benefit where it is impossible properly to isolate a primary case, or when the infection is introduced into an institution in which a number of susceptible individuals are congregated.

Chelmsford.

THE ROENTGEN RAYS IN SOUTH AFRICA.

BY J. HALL-EDWARDS, L.R.C.P. EDIN.,
SURGEON RADIOGRAPHER TO THE GENERAL HOSPITAL, BIRMINGHAM, AND TO THE IMPERIAL YEOMANRY HOSPITALS AT DEELFONTEIN AND PRETORIA, SOUTH AFRICA.

AN experience of 14 months as x-ray expert to the Imperial Yeomanry Hospitals at Deelfontein and Pretoria has amply proved the immense usefulness of Roentgen's discovery as applied to military surgery. On starting from England I had already formed some idea as to the extent to which my speciality might be of service, but my wildest anticipations were exceeded and my preconceived notions born of ignorance, and backed up by the officials at the War Office, have proved to be incorrect and absolutely unsatisfactory. On information received from certain pseudo-reliable sources I was convinced that so few bullets found their billets in the tissues of the wounded that an x-ray outfit would prove an incumbrance instead of a help, and although I had some hopes that my ideas might prove incorrect I entered upon my task with fear and trembling. These fears were magnified when on reaching Cape Town we were informed that Cronje had been captured and Ladysmith relieved and that the war could not last more than a few weeks. This last statement, like those received at home, was far from true, and whilst it was given in good faith, it was the child of ignorance, born in the cradle manufactured by our Intelligence Department.

I well remember remarking to an officer (on the Government landing-stage at Cape Town), who had been my companion since leaving England and who was wishing me adieu and success, "that if I could take back with me five negatives showing the presence of bullets, I should consider my visit to South Africa more than justified." It would be exceedingly difficult even to guess the percentage of retained bullets in all gunshot wounds, but there can be no doubt that it is far higher than is generally imagined, although taking into consideration the number of wounds received it must be very small. My own figures cannot, of course, be taken as any guide, inasmuch as I only radiographed cases specially sent to me for the purpose, a large majority of the cases admitted to the hospital not being of sufficient interest to warrant the taking of a radiograph. In several of these bullets which could be localised by palpation were removed without the aid of the x rays and they therefore take no part in my calculations. In all, 193 cases of gunshot or shell wounds were submitted to me and in 65 of these there were found and localised, either a whole bullet, portions of a bullet, or fragments of shell. This is, of course, an exceptionally large percentage which can only be accounted for by the assumption that many cases in which the presence of a bullet was suspected were sent to us for the purpose of having them localised. It is absolutely impossible to form any idea of the percentage of retained bullets in wounds received; neither can I satisfy myself as to the range at which most bullets are retained. Bullets which are nearly spent have, of course, the greatest chance of remaining in the tissues, but the ranges given in my notes are so various that many other circumstances must combine to diminish the penetrative power, even at distances where under ordinary conditions they would pass through the body. In previous articles on this subject I have pointed to some of these and a careful perusal of the accompanying table may suggest others.

List of Cases of Injury, with Bullets, Portions of Bullets, and Fragments of Shell, Radiographed at the Imperial Yoemanry Hospitals at Deelfontein and Pretoria, between March 19th, 1900, and March 31st, 1901.

Parts injured.	Number of cases radiographed	Number of cases in which foreign bodies were localised.
Eye	3	1
Head	11	1
Neck	2	1
Chest	18	7
Shoulder ...	10	1
Arm	13	4
Elbow	14	2
Forearm ...	10	1
Wrist	3	0
Hand	19	8
Abdomen ...	2	0
Spine	1	1
Back	5	3
Pelvis	6	4
Thigh and hip	30	18
Knee	8	3
Leg	16	8
Ankle		0
Foot	18	2
Total... ...	193	65

The list here given is not a long one, but is must be remembered that in most of these cases the presence of a foreign body was suspected. Many other cases were examined in order to ascertain the amount of injury sustained by bone during the passage of bullets through it, and in addition to several medical cases over 50 accidental fractures were radiographed. Again, during the greater part of our stay in the Karroo we were to all intents and purposes a base hospital, and all the cases had filtered through other hospitals before coming to us. It was only during the last two months that we received any wounded straight from the field, and curiously enough none of these came into my hands

The list is exceedingly interesting in showing that by far the larger majority of bullets retained in the tissues are found between the ankle and abdomen, whilst the upper extremities are comparatively free, with the exception of the hand. Here only in one instance was a whole bullet retained, the remainder being in the main splinters from bullets which had struck stones in front of the fighting line, and as in most cases the men were lying down the hands and heads were chiefly exposed Where the head was struck the result was in a very large majority of instances fatal, although a good number of these escaped, as is shown by my figures. In nearly every instance where a bullet was retained in the hip or thigh the whole of the missile was found. In more than three-fourths of the cases in which foreign bodies were localised they were removed by the operating surgeons and in no single instance was the object sought after missed. The position of the bullet was marked upon the skin and the depth from the skin was accurately ascertained. The only difficulty that can possibly arise after an exact and carefully made localisation where the bullet is near the bone is (even when the depth from the surface is known) that of deciding whether or not it is embedded in the bone itself. To decide this without preparing a pair of stereoscopic prints one must rely entire upon one's knowledge of anatomy; not that it is of very great consequence, for having decided that it is better for the patient that the bullet should be removed it is only necessary to be prepared for possibilities. A case in point occurred in a young soldier who was shot in the neighbourhood of the hip-joint. An x-ray localisation showed the bullet apparently lying across the neck of the femur, at the depth of five and a half inches from the buttock. A long consultation failed to show its exact position in relation to the bone, but it was decided to operate. The surgeon cut down upon the spot and found the bullet firmly embedded. It was removed and the patient made a complete recovery. Had it been possible to prepare a pair of pictures which could have been viewed in the reflecting stereoscope the question would have been at once settled, for by this method the exact relations would have been seen. The preparation of such pictures, of course, involves considerable trouble, but I am more than ever convinced that a reflecting stereoscope must in future form part of a base hospital equipment, for although in most cases measurements are amply sufficient there are undoubtedly occasions when it would prove of the greatest possible use.

Localisation by means of the x rays is based upon mathematical calculations and is so absolutely correct that I cannot imagine any surgeon even daring to consider any other method. Yet I am constantly hearing of the telephone probe, the latest competitor in the field of prehistoric instruments which even under the old conditions of warfare were bad, and under the new are worse than useless. There is no position in the body in which a bullet cannot be found and exactly localised by means of the x rays. Moreover, this can be done without disturbing the patient or subjecting him to anything but the slightest inconvenience for at the most 10 minutes. He runs no risk of infection from dirty probes and the results are absolute. The telephone probe is alone useful for finding a bullet when its position is known, and may on occasion prove of slight assistance during an operation when the bullet is in a difficult position to get at and cannot be seen. I am pleased to say that at The Imperial Yeomanry Hospital the telephone probe was never used, and yet in every instance in which the operating surgeon was called in the bullet was found.

In a previous article published in THE LANCET of Jan. 12th (p. 130) I drew attention to the inefficiency of the x-ray arrangements made by the War Office, and it is only since my return home that I have seen the reply of Colonel W. F. Stevenson, R.A.M.C., in which I am pleased to see that he quite agrees with me, that if an x-ray specialist is to be of any service he must devote the whole of his time to the subject. As regards the x-ray department which I am informed exists, I would like to ask how it is that experts were not turned out from there? and why it was necessary to employ laymen to do the work? Surely the fact than an expert must spend his whole time at the work should have been recognised years ago. Again, as regards (what I still dare to call) the so-called experts. I have before me three letters from the War Office, dated respectively Oct. 31st, Nov. 23rd, and Dec. 30th, 1899, informing me that experts were not required. Again, late in January, 1900, my services were refused, whilst those of medical students and manufacturers of apparatus were accepted at the princely income of £200 per annum. I do not wish to argue for one moment that these men have not done good work; but I again say that they can in no way be considered as experts.

I did not say that the apparatus sent out by the War Office was not good or that an insufficient number of sets were supplied, but I know that some of the sets were never used, whilst others were only used occasionally. During the whole of my stay at Deelfontein there was an apparatus at De Aar which I was told on the authority of the principal medical officer was never used. On the occasion of my first visit to Kimberley I found a gentleman in charge who was uninformed as to the use of the localising apparatus; and since then I have received a letter from another gentleman in charge of the same department asking me to give him some instruction. At a large hospital in Pretoria I found the Mackenzie-Davidson cross-thread localiser was being used as a developing table upon which the staff developed their Kodak films and, finally, I left my department at Deelfontein with no one in charge. These facts speak for themselves, and yet I am told that the War Office has a properly equipped x-ray department. In laying these facts before the readers of THE LANCET I have no intention of injuring or hurting anyone's feelings, they are written with the hope of bringing about a better order of things; and when the much-talked-of reform in the Army Medical Department is brought about I trust that this most useful adjunct to military surgery will not be forgotten.

That our x-ray department proved a success has already been testified to by our senior surgeon (Mr. A. D. Fripp, C.B.), who in his letters to the medical press has described it as "the most useful department in the hospital"; and I am sure that Mr. Raymond Johnson, Mr. H. A. Ballance, Mr. William Turner, and Mr. A. P. Parker would admit that some of the best surgery was the outcome of work done there; and I, moreover, feel certain that the figures herein published will go to prove that as an aid and necessity to military surgery the x rays must take the premier position.

Birmingham.

ANEURYSM OF THE SUBCLAVIAN AND AXILLARY ARTERIES: LIGATURE OF THE SECOND PART OF THE SUBCLAVIAN.

BY G. A. WRIGHT, M.B. OXON., F.R.C.S. ENG.,
SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND PROFESSOR OF SYSTEMATIC SURGERY IN OWENS COLLEGE

AND

P. R. WRIGLEY, M.R.C.S. ENG., L.R.C.P. LOND.,
LATE HOUSE SURGEON TO THE MANCHESTER ROYAL INFIRMARY.

A MAN, aged 36 years, was admitted into the Manchester Royal Infirmary on Dec. 12th, 1900, complaining of "swelling of the main artery of the left arm." The appearance of the patient was that of a strong vigorous man, giving no history and presenting no signs of syphilis. His occupation necessitated the occasional lifting of heavy sacks of flour (240 lb.). He told us that in May, 1900, he first noticed pain in the left shoulder over the acromion, which was worse in the evening than on rising in the morning. He had the shoulder rubbed and as the pain disappeared entirely in two or three weeks he thought no more of it until in September the pain returned in greater severity. At first the trouble was looked upon as rheumatic, but in December the presence of aneurysm was recognised and he was sent to the infirmary.

On admission on Dec. 12th, the patient complained of pain in the left acromial region shooting down the arm into the left breast and the back of the neck. On examination there was found to be no difference in the muscular power of the two arms and hands and there was neither wasting nor œdema of the left hand and arm. Sensation, too, was quite normal. In the left clavicular region there was an extensive swelling stretching some distance above and below the clavicle and so prominent that the outer two-thirds of the clavicle were not apparent on inspection. Pulsation could be observed over the whole swelling. On palpation the swelling was found to be more extensive below than above the clavicle and to be both expansile and pulsatile. The swelling could be grasped by one hand just beneath the clavicle with the other pressing deeply in the axilla when the expansile pulsation could be felt in the axilla, which could also be felt in the posterior triangle of the neck. On compressing the third part of the subclavian artery between the finger and the first rib pulsation in the tumour was completely stopped, but the artery in its third part was evidently dilated. On percussion there was a dull area on the left side of the chest extending from the clavicle to one and a half inches below it and from the anterior axillary fold to within three and a half inches of the middle line of the body. On auscultation a harsh systolic bruit could be heard.

An operation was performed on Dec. 19th. The patient was prepared for this in the ordinary manner and chloroform was administered. The head was then pushed over to the right and the left arm was brought down to the side An incision four inches long was made at the upper margin of the clavicle, between the attachments of the trapezius and sterno-mastoid muscles, dividing the skin and superficial fascia The platysma and deep fascia were divided, the external jugular vein being exposed and divided between ligatures, as was also the supra-scapular vein The posterior belly of the omohyoid then came into view and was found to be much lower down than usual, with the subclavian artery high up. At this step the skin incision was enlarged and the clavicular origin of the sterno-mastoid was partially divided. The posterior belly of the omohyoid was retracted upwards and the scalenus anticus, which now came into view was retracted forwards. The subclavian artery in its third part was then distinctly seen and by following this upwards the second part was found to be of normal diameter, but the third part was greatly dilated The second part of the subclavian artery was then compressed and pulsation in the positions in which it had previously been palpable and in the dilated portion of the artery at once ceased.

After opening the sheath of the artery an aneurysm needle was passed round the second part of the artery from below upwards and threaded with "pedicle" silk and two ligatures were passed. The ligature nearest the heart was first tied, as far from the aneurysm as possible, and the second ligature was tied close to it Both these ligatures were tied in such a manner as to approximate the arterial walls without rupturing their coats and the free ends of the ligatures were tied together. All bleeding from the small vessels that had not been previously controlled was stopped and the wound was well washed out with biniodide of mercury lotion of the strength of 1 in 6000. The edges of the wound were then brought into apposition with silk sutures and the wound was dressed with dry dressing The whole of the left hand and arm was then covered with cotton-wool and lightly bandaged with domette bandages and the limb was supported across the chest.

As there were no unfavourable symptoms the dressings were not removed until Dec. 30th, the eleventh day after operation, when it was found that the wound had completely healed; the sutures were removed and light dressing was applied The aneurysm was much smaller in size and no longer pulsated. The radial pulse had not yet returned. On Jan. 26th, 1901, the patient was discharged from the infirmary convalescent; the circulation in the left arm and hand was good, though the radial pulse had not yet returned There was no sign of pulsation in the site of the aneurysm When seen on Feb. 26th there was still a slight bulging in the position of the aneurysm, but this swelling was firmer, harder, and non pulsatile. There was now very slight pulsation in the left radial artery. The patient was advised still to make use of a sling but to attempt slight movements of the arm and hand.

Remarks by MR. WRIGHT —From the notes (for which I am indebted to my then house surgeon, Mr. Wrigley) it will be seen that it was necessary to tie the second part of the subclavian in this case on account of the dilatation of the third part of the artery. This was not much more than a nominal difference as extension of the wound forwards and retraction of the scalenus enabled us to reach a very high artery at a point where it was healthy. We were anxious as to the condition of the artery beyond the ligature since it was greatly dilated, but the dilatation began somewhat suddenly and the part tied was natural in size Thick silk was used and the principle of the "stay knot" was adopted without division of the coats of the vessel The thick "pedicle" silk made a somewhat bulky ligature, but healing went on without trouble. We had the advantage of the help of Mr A. H Burgess, now surgeon to Crumpsall Hospital, at the operation

WESTMINSTER HOSPITAL FESTIVAL DINNER.—On June 12th the Duke of Buccleuch presided at the festival dinner of this institution at the Salters' Hall St. Swithin's-lane, E C. The chairman, in proposing the toast of the evening, said that several additional rooms for scientific purposes had been added to Westminster Hospital in recent years and he thought that at the present time the hospital might be considered equal to all modern requirements During the evening the secretary announced contributions amounting to about £8500

MEAT PREPARATIONS: THE POSSIBILITIES OF MYOSIN ALBUMIN.

BY F. W. FORBES ROSS, M.D. EDIN., D.P.H R C.P.S LOND.

FOOD problems at the present time possess a peculiar interest alike for the medical and the lay mind. The main desiderata are: for the former, physiological efficiency, nutritive, formative, reparative, and stimulative powers in all directions compatible with the minimum of effort in assimilation; for the latter, efficiency, cheapness, and portability. From the above two points of view nothing comprised in the dietary of mankind possesses so many points of technical interest as meat, particularly those qualities of a meat diet mentioned above. This is especially the case when dealing with preserved meat preparations or preparations of meat which are not readily and easily made and are therefore kept put up in specially desired forms ready for consumption at a moment's notice

Extractive compounds —The more commonly obtainable and popular preparations, or meat extracts, are all slight variants of, and are made from, a single preparation which is mainly composed of urea, uric acid, sarcolactic acid, *creatin*, *creatinin*, *xanthin*, *hypoxanthin*, *taurin*, &c. *These* elements, belonging as they do to the waste-product compounds, possess properties which are mainly stimulative; their action rests mainly in calling up effort from already stored energy to which they could only very partially if at all contribute, the effort of the organism being for the most part aimed at their excretion and expulsion. This effort can at times be voluntarily switched off, so to speak, from being an effort of excretion into a motor or mental channel From the above it can easily be seen that their effect when partaken of can only be one of very short duration, indeed, the more frequently the dose be repeated the shorter become the periods of their functional utility—that is, provided they are not at the same time reinforced by food substances the functions of which are mainly nutritive, formative, and reparative, in order to repair the wear and tear which are the results of forced energy brought about by the administration of extractives Eventually, if their sole administration be continued, they begin at last actively to exhaust and to break down tissue, because having used up stored materials and energy they make demands for their excretion which must be and are answered by destructive metabolism of formed tissue existing within the organism and if now the excretory power fails they accumulate and become poisonous. This is easily demonstrated by the dieting of dogs, some on stimulant extractive alone and others on stimulant *extractive in combination with nutritive* and formative albuminous meat compounds, and then noting the results The latter are not adversely affected, in some cases being distinctly benefited, whilst the former rapidly emaciate and die and are even outlived by dogs simply starved and only allowed water. The same is observed in the feeding of enteric fever patients on stimulant extractives alone, *for in addition to the already heavy load* of "waste products" incidental to their disease which demands removal any addition of a purely extractive diet is often followed by signs of exhaustion of excretive power, and symptoms of accumulated waste-product poisoning supervene.

I once personally experimented on a diet composed solely of commercial stimulant meat extract, but on the sixth day abandoned the attempt after a syncopal attack, the result of the deprivation of material to repair the wear and tear of tissue Extractive meat preparations, like most other stimulants, are also to a certain extent irritants when given alone or in too great a proportion in combination. On patients suffering from gastric irritability, catarrh, &c, even on some healthy persons and children, stimulant extract will often act as an emetic, and if repeated will set up diarrhœa. This latter action is, perhaps, as much the result of its being in part irritant when strong, and stimulant to the excretory and motor functions of the intestine and liver, as to the fact that, according to Professor A E Wright of Netley,[1] much peptone entering the blood-stream at one time leads to outflow from the blood-vessels, causing diarrhœa. The above also refers equally to the action of many peptonised meat preparations (albumoses) in producing diarrhœa if their administration be persisted in.[2] The stimulant extractive or waste product compounds of meat nevertheless occupy a position of utility within certain limits which is undoubted. If they act only as excitors of convertible energy they are useful in that they lead to functional activity which may be expended in assimilating the nutritive and formative components of meat provided the latter be present or obtainable.[3]

---

[1] Serous Hæmorrhage: THE LANCET, Sept. 19th, 1896, p. 807.

Gelatin.—Midway between the extractives and albumins from a dietetic point of view comes gelatin. Till recently gelatin was supposed to have little or no claim to functional nutrition, and at most was regarded as a substance used by the organism as a "stand-by" to prevent destructive metabolism of formed tissue in the absence of circulating surplus proteid.[4] Lately, however, opinion is more in favour of gelatin being after all of distinct food value, how much merely stimulant and how much really nutritive and formative is still a matter to be settled.

Albumins.—The albumins, globulins, and paraglobulins of muscle plasma have a distinct and decided function as nutritive, formative, and reparative agents. Their position as food substances in every acceptation of the term is indicated by their large proportion in meat food. Their near resemblance to the higher protoplasmic elements of the more elaborated nerve tissue, their close connexion therewith, their marked resemblance in saline constituents—e.g., phosphates—their complex functions as motor, heat-producing, oxidising, and waste-product destroying agents, all tend to point them out as food ingredients of the highest possible value. Albumins most probably play a great part in furnishing the materials of the various secretions. The above are all well shown in the defective functions and diminished vitality, debility, and chronic ill-health of persons whose muscular system has been allowed to fall into want of tone through disuse, and the prompt improvement which occurs on renewing their tone, bulk, and function by proper feeding, development, and exercise. The foregoing tends to point clearly to the great value and benefits to be derived from the use of the albumins of muscle as an addition to meat preparations intended for general consumption, in a condition as near their natural state as they exist in the living creature, unaltered by chemical or predigestive processes. The food best adapted for the maintenance of prolonged muscular effort and for the repair of the resulting wear and tear is a diet of meat albumin; hence the preference of those in "training" for "beefsteak," and the marked benefit to be obtained by feeding on myosin albumin in cases of heart-failure, especially in elderly persons who have been unable to eat meat and have taken to milk-slops owing to loss of teeth or badly fitting false teeth through senile absorption of the alveolar borders of the jaw.[5] Milk or casein albumin, though excellent as an article of diet for infants, does not furnish the necessary food equivalent for the adult. Milk is nature's food for the infant; muscularity is not the leading feature of the infant; muscularity is the distinctive feature of the adult; consequently milk cannot be safely assumed to be a satisfactory food substance for adults without reinforcement from other food sources. It is well known that milk as a sole article of diet cannot support life in an adult for a longer period than from four to six weeks. On the other hand, the albumins of meat can be given to children past the first year of life with benefit and safety during long periods. If the mixed albumins designated by the comprehensive term "myosin albumin" were extracted from meat and exhibited in various forms and combinations with or without suitable proportions of extractives and gelatin, they would lend themselves in a number of ways to the prospective solution of many problems. The system of manufacture of meat preparations now practised is to subtract one solitary constituent property from meat, and in some cases from blood, and that constituent not the most valuable, and then to speak of "concentration" which is really the reverse, as it amounts to "fractional distillation," resulting in the discarding of the more nutritive, formative, and reparative elements (albumins) in favour of the less useful stimulative elements which now masquerade as "concentrated meat extract."

Emergency rations.—The problem of an efficient emergency ration for soldiers, tourists, cyclists, travellers at home and abroad, and for anyone who desires to carry concentrated food of high nutritive value can be solved by the use of myosin albumin suitably combined and seasoned. Here the stimulant, nutritive, formative, and reparative constituents of fresh beef alone take the place of the more bulky canned meat with its 70 per cent. of fibrous matter, possessing little food value in comparative proportion. By this means one pound weight of steak can be carried in a made-up compound ration of four ounces in weight (nett), and be palatable and relatively of more utility under the circumstances than one pound of meat, as it can be digested and assimilated more easily. That there is need and room for such a ration is proved by a letter by Captain J. H. E. Austin, R.A.M.C.,[6] on the feeding of soldiers on the march, in which such a ration is demanded. At the same time a ration of myosin albumin lends itself to variety, for the ration can be made into good soup or stew with meal, pea-meal, biscuit, or desiccated vegetables.

In the treatment of disease myosin albumin can be used as a reinforcement to milk puddings for invalids, heart cases, &c., as it can be made absolutely tasteless. With boiled biscuit, egg, and cream it makes a delicious panada. When persons suffering from the effects of "gout" abstain from eating ordinary meat by reason of the uric acid and waste products it is said to contain in a free state, yet who need meat and the iron albumins of meat, as in senile heart failure cases, then the difficulty can be met, as myosin albumin can be so treated by dialysis, &c., as to free it from all natural extractive and waste products and so render it desirable as an article of diet for those of the gouty diathesis. In the treatment of enteric cases I have had opportunity of judging its action,[7] and have found it an efficient means of supplying the needed energy to carry on the functions and secretions of the body and at the same time to repair waste. In the treatment of tuberculosis the value of meat albumin is undoubted, not only as a means of repair, but also as a direct strengthener of the forces of resistance already present in the body. Dr. Parkes Weber[8] speaks highly of meat albumin in the treatment of tuberculosis, and so does Djvorack.[9] Héricourt Richet's[10] experiments on dogs are of value, though he attaches great importance to the rawness of the meat. In a case published by Dr. Fletcher Little and myself[11] in THE LANCET, myosin albumin was used with success prior to the prescription of the open-air treatment, and the case did remarkably well and the patient rapidly gained weight even after residence abroad had failed to benefit. Perhaps it is that, apart from the theory of natural somato-antitoxin, raw meat gives up its albumins quicker than does toughened cooked meat and that, as in the case above cited, if sufficient albumin at a time be forthcoming in response to a minimum of digestive effort, then the results will in all probability improve *pari passu*.

The foregoing will, I trust, serve to indicate the field of utility open to myosin albumin in food problems of the future, whether as emergency ration, general meat extract, or specific preparations for invalids and young persons. Hitherto it has been mainly absent, wholly or in part, from existing meat preparations, and where alleged to be present has been too expensive to suit any but the pockets of the richest. It yet remains to devise a suitable, cheap, and economical process for extracting and dealing with "myosin albumin" in bulk as a commercial proposition, and thereby to bring it within general reach as a constituent of meat preparations of the highest nutritive, formative, and reparative value.

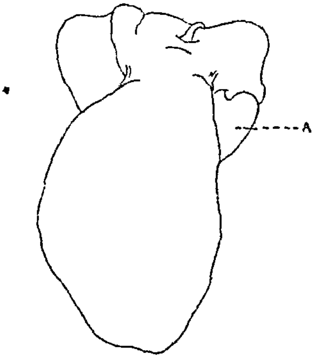
CHARING CROSS HOSPITAL.—A concert was given in Stafford House on June 11th in aid of the special fund for Charing Cross Hospital. The picture-galleries were thrown open to the visitors and tea was served in the dining-room and the garden.

A NOTE ON A CASE OF FIBROMA OF THE SMALL OMENTUM

BY J JACKSON CLARKE, M B LOND, F R C S ENG,
ASSISTANT SURGEON AT THE NORTH WEST LONDON HOSPITAL
AND AT THE CITY OF LONDON ORTHOPÆDIC HOSPITAL.

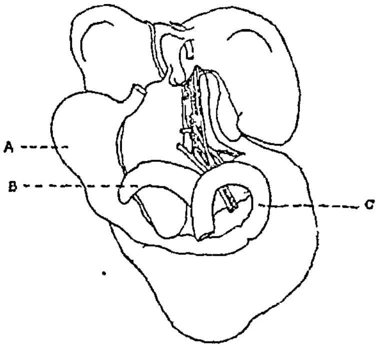
IN the Transactions of the Royal Medical and Chirurgical Society for the year 1900, Mr Pearce Gould has recorded a case that is not only remarkable in itself but also lends a reflected interest to a case that I communicated to the Pathological Society of London in the year 1892 Since Mr Pearce Gould, in the record of his case of sarcoma of the gastro-hepatic omentum, has fully quoted the pathological account of my specimen as well as the comments that I made upon the surgical anatomy of the tumour, the only reason that I have for bringing the subject forward again is that I may remove a defect from the record of my case as it now stands in the place above referred to Mr. Pearce Gould has drawn attention to this defect by expressing regret that in my account no details of the alteration in the position and shape of the stomach and duodenum or any exact account of the state of the portal vessels and *common bile-duct* are given *It is fitting to* state that these details were included in sketches that I exhibited with the tumour before the Pathological Society of London With these sketches before me I can now state that the stomach was of an elongated and narrowed form, the greater part of it lying obliquely behind the tumour This elongation of the stomach resulted in the pylorus being at a much greater distance from the cardiac orifice than is normally the case The pylorus lay behind the growth, a little to the right of its median line and about the junction of its lower and middle thirds From the pylorus the duodenum passed first upwards, then to the left, and finally downwards, completing three fourths of a circle The opening of the common bile duct into the duodenum was situated vertically above the pylorus in the middle of the horizontal portion The common bile duct, the hepatic artery, and the portal vein were elongated and lay behind the upper half of the tumour near its right border The main arterial supply of the growth was an offshoot of the gastro duodenal branch of the hepatic artery There was a hepatic branch of the superior mesenteric artery which ran up behind the portal vein to the liver

FIG 1



The tumour and the liver and the cardiac end of the stomach (A seen from the front.

FIG. 2



The liver, the stomach and duodenum, the pancreas, and the tumour seen from behind The structures in the right border of the small omentum have been exposed by dissecting away the posterior layer of peritoneum. A = stomach, B = pancreas, C = duodenum.

WESTMINSTER HOSPITAL

A CASE OF PYÆMIA AFTER ABORTION IN WHICH THE PERICARDIUM AND THE LEFT PLEURA WERE OPENED AND DRAINED, DEATH

(Under the care of Dr W A WILLS and Mr W G SPENCER)

DRAINAGE of the pericardial cavity is still an extremely rare operation, though several of those that have been described have been very successful It is now generally recognised that it is very difficult to aspirate the pericardium on account of the tendency manifested by the heart to float towards the sternum when the patient is in the recumbent posture The following case illustrates the importance of ascertaining the nature of the micro-organism present in a case of septicæmia or pyæmia, for we have no reason to think that anti streptococcic serum would be of any avail in infection due to a staphylococcus For the notes of the case we are indebted to Mr H Hallilay, house physician

A married woman aged 24 years, with six children, was admitted into Westminster Hospital on April 4th, 1901, under the care of Dr de Havilland Hall and during his absence came under the charge of Dr Wills The patient was in her usual health until a fortnight before admission She then was attacked by malaise, joint pains, and feverishness, and took to her bed at once She was three months pregnant and at the end of the first week of her illness she had a miscarriage She had had no vaginal discharge before, but after the miscarriage a discharge came on and lasted for about a fortnight She was admitted as suffering from acute rheumatism with pericarditis

She was a stout somewhat florid woman Her temperature was 103° F There was considerable dyspnœa Her face was livid and the alæ nasi were working She was sweating freely but there were no joint pains There were evident signs of pericardial effusion, the præcordial dulness extending to the left just beyond the nipple line and upwards to the upper border of the third costal cartilage The impulse was feeble and diffuse There was a distinct pericardial rub heard at the left margin of the sternum over the base of the heart and the heart sounds were muffled but clear From the angle of the scapula to the base of the left lung there were dulness, whiffy tubular breathing, and bronchophony, with some increase of vocal *fremitus* pointing to pneumonic consolidation of the left lower lobe Elsewhere over the lungs there were no abnormal physical signs The pericardial effusion did not appear to be sufficient to account for the dyspnœa and lividity, but these no doubt were due to the lung being also involved.

During the next week the patient's general condition improved somewhat. Her appetite was remarkably good and she took solid food readily, but her breath remained very short. The signs of consolidation at the left base had almost entirely disappeared, but there was impaired resonance with some tubular breathing and a few râles at the end of inspiration at the right base. The præcordial dulness had extended to half an inch beyond the nipple line; the pericardial rub was still audible. The diagnosis of septicæmia after a miscarriage had by this time been provisionally made, though the patient's statements about the date of this event were so contradictory, varying from a fortnight to six weeks previously, that there was still some uncertainty. However, on April 15th two abscesses were found, one on the back of the right shoulder and the other over the left hip. They were opened and drained, being found to contain thick yellow pus.

On April 17th 10 cubic centimetres of anti-streptococcic serum were injected into the cellular tissue of the abdomen. The patient's general condition continued very good, with the exception of much dyspnœa and lividity on the least exertion. The physical signs at the right base had nearly gone, but at the left base signs of effusion had succeeded to those of pneumonia, though the amount of fluid did not appear to be large. A rapid increase of the already large area of præcordial dulness now took place, the left margin reaching to the anterior axillary line, the right border being one inch beyond the right edge of the sternum and the upper limit being the second left costal cartilage. At the same time the heart sounds became extremely muffled, much more so than at any previous period of the pericardial effusion. Her temperature since admission had ranged between 103° and normal, but until the last five days had rarely risen above 101°. Her pulse averaged from 140 to 160 and her respirations from 40 to 60. As it was clear that she was suffering from pyæmia, as evidenced by the two abscesses which had been opened and the signs of infection of the pleural and pericardial sacs, it was thought probable that the distension of the pericardium was due to a purulent rather than to a serous effusion, and as the heart's action during the last 24 hours had shown some signs of failing Dr. Wills decided to ask Mr. Spencer to open and to drain the pericardium. On the 19th she was accordingly transferred to his charge.

Mr. Spencer found no external signs of the pericardial empyema, in particular no œdema over the sternum. The patient was given a little ether which did not increase the dyspnœa or the pulse-disturbance. An angular incision was made down the left side of the sternum and outwards along the costal margin. This incision was required as there were much subcutaneous fat and a heavy dependent breast which had to be retracted upwards and outwards. The fifth left rib cartilage was then excised and the internal mammary artery was tied above and below. Behind the rib appeared the parietal pleura and through it was seen the edge of the lung, whilst all that could be felt with the finger at that stage seemed like the base of the heart. The sixth rib cartilage was next removed, but behind it only the diaphragm was found. Thus, so far, the distended pericardium had not come into view. Thereupon the patient was turned on the side and the left pleura was opened by removing a piece of the seventh rib in the post-scapular line. Turbid sanious fluid escaped from the pleura: there was no fibrin or adhesion and the lung quickly expanded. On exploring the pleural cavity with the finger the dome of the diaphragm was felt and above it the tensely distended pericardium behind the heart. An attempt was made to thrust a long aspirating needle into the pericardium, but it only stuck in the diaphragm. The patient was therefore again turned on to the back, the parietal pleura behind the fifth rib cartilage was opened, the edge of the lung was pushed aside, and the parietal pericardium incised. As before mentioned, it seemed as if one was incising the pericardium at the base of the heart. It proved to be about a quarter of an inch thick; on entering the cavity the wall of the heart was immediately reached, the parietal and visceral surface being partly adherent by recent fibrin. The heart was of normal size; on passing the finger round the apex the distended portion of the pericardium was reached and purulent fluid escaped freely. From a portion of the first which escaped a pure cultivation of staphylococcus pyogenes aureus was obtained. The pericardial differed from the pleural empyema in the fibrin and adhesions present. A large drainage-tube was quickly inserted past the apex of the heart into the cavity behind, and a strip of gauze was inserted into the pleura.

The patient, without being markedly improved by the operation, for a fortnight maintained her strength till about a week before death. Pus and fibrinous shreds escaped freely through the pericardial tube. The cavity was washed out daily by alternately injecting water and sucking it out again. At first she was supported by pillows, so that the cavity drained, but it did not empty completely when she became more prostrate. The pleural wound discharged very little; the lung fully expanded and as shown post mortem the communication in front was shut off. About a week before death another abscess formed deep in her right buttock, but this, owing to her weakness, was only aspirated.

Post-mortem examination by Dr. W. S. LAZARUS-BARLOW.—The body was found to be well nourished. There were a surgical incision in the præcordial area which discharged pus from the pericardium and a small incision in the right suprascapular region. The pleural cavities were fairly free from adhesions. The lungs were small and were collapsed at the lower edge of the left lower lobe. The upper part of this lung and the whole of the right were normal. The larynx, trachea, and bronchi were normal. The pericardium was thickened and in places the two layers were adherent, everywhere being covered by a thick layer of curdy material. Free pus was present in the non-adherent parts of the cavity. The heart was of normal size; the myocardium was pale; the valves were normal. The liver was fatty and showed early cardiac changes. The spleen was large and soft. The pancreas was normal. The kidneys showed a cloudy swelling. The stomach and intestines were normal. As regards the uterus, the endometrium was congested, the wall was pale, the cervix was dilated, and the os was patulous. The tubes were congested. The ovaries were normal.

Remarks by Dr. WILLS.—The number of recorded cases of pericardial drainage is not large so it has been thought advisable to publish this account of the operation. As the patient was clearly suffering from pyæmia, when the operation was decided on it was considered better to make a free opening into the pericardium at once, without any preliminary attempt to ascertain the nature of the fluid by the use of an exploring syringe. The information thus obtained is so apt to be misleading, owing to the probability that the pus, unless in very large amount, will gravitate to the back of the pericardial sac, on account of the necessarily recumbent position of the patient, that it was felt to be unwise to risk the damage which might be caused by puncturing the heart wall. This has often been done without any harm resulting, but the likelihood of its occurring even when fluid is present in the sac, but present in the back of the sac rather than evenly diffused, is so great as to render the negative evidence of fluid so obtained of very little value. Moreover, the comparatively small needle which must be used for fear of the possible puncture of the heart wall being dangerous if large is so likely to be blocked by shreds of lymph that a further element of uncertainty is introduced in this way.

Remarks by Mr. SPENCER.—This case is surgically noteworthy as an instance of the collection of fluid almost entirely behind the heart; hence there was no appearance of a distended pericardium on the removal of the fifth rib. It proved, however, as in previous cases, that the fifth rib was the proper one to remove in order to expose the pericardium. If the patient had recovered somewhat a further operation would have been needed to have got rid of the cavity behind the heart, as the parietal wall of the pericardium was so thick and rigid. It would probably have become necessary to cut away the lower portion of the pericardium.

The diagnosis was based entirely upon the physical signs noted by Dr. Wills. It is very fortunate that no attempt was made to explore the pericardium with an aspirating needle Had this been done through the fourth or fifth interspace close to the sternum considerable resistance would have been met with in passing through the pericardium and the needle would most certainly have gone on into the heart wall, for there was practically no fluid between the pericardium and the heart in front, only a layer of fibrin with fluid in its meshes. The distension of the sac was behind, out of reach of an aspirating needle.

GLASGOW ROYAL INFIRMARY.

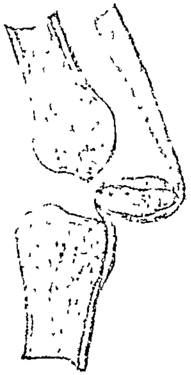
TWO CASES OF DISLOCATION OF THE PATELLA, ONE UPWARDS AND ONE DOWNWARDS.

(Under the care of Dr. DAVID NEWMAN and Dr. HENRY RUTHERFURD.)

THE exceeding rarity of these forms of dislocation of the patella is manifest from the total absence of any description of them from the text-books. Either form must require a direct blow on the patella, and this blow must probably be delivered in a nearly vertical direction, either upwards or downwards, according to the variety of dislocation produced.

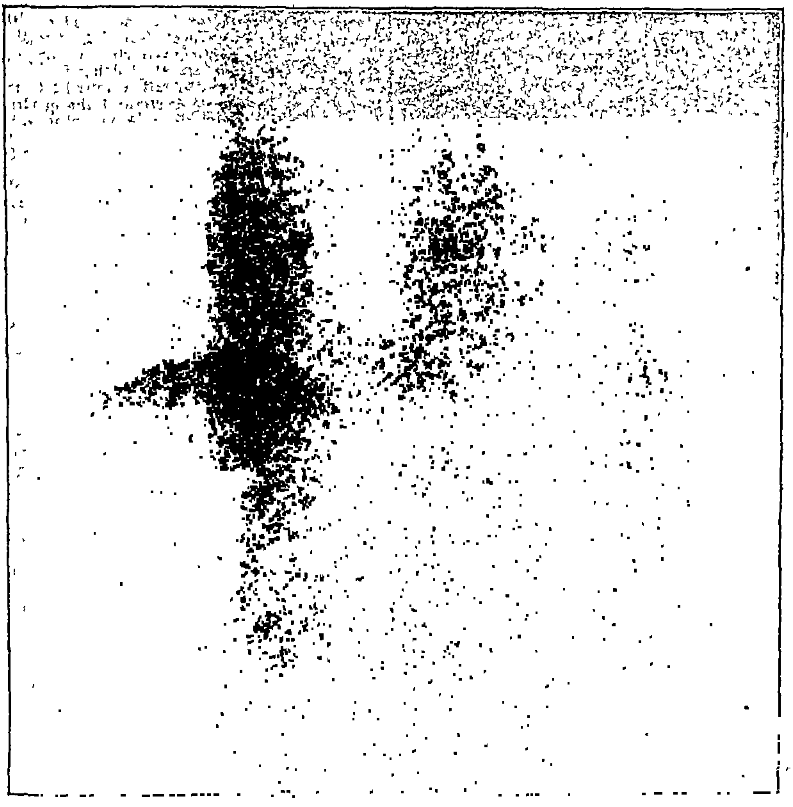
CASE 1. *Dislocation of the patella upwards by rotation on its horizontal axis, the articular surface presenting upwards.*—A man, aged 24 years, was on Oct. 24th, 1900, admitted into the Glasgow Royal Infirmary under the care of Dr. David Newman complaining of an injury to the right knee-joint. The history of the accident given by the patient was that a few days prior to admission he fell and injured his right knee which he said had been weak as the result of an injury received six years ago. On examination the knee was seen to be swollen and the slightest pressure with the hand caused the patient great pain. The knee while at rest assumed a slightly flexed position and without the employment of an anæsthetic the joint could not be further flexed or extended. Two days after admission the patient was placed under chloroform and the knee-joint was examined. Dr. Newman found that

FIG. 1.



Section of the knee-joint, showing dislocation of the patella upwards in Case 1.

FIG. 2.



Skiagram (lateral) showing the dislocation of the patella downwards in Case 2. The upper border is engaged between the femur and the tibia.

while the lower border of the patella was wedged in between the head of the tibia and the condyles of the femur there was an abrupt hollow immediately below the dislocated bone, and the ligamentum patellæ lay close to the head of the tibia, while the tendon of the quadriceps extensor muscle was thrown forwards and rendered unduly prominent. On both sides of the tendon there was a deep groove. Fig. 1 shows a section of the knee-joint in its middle line. The condyles are not represented, being shown as a section through the inter-condyloid notch. The apex of the patella was wedged between the head of the tibia and the adjacent surfaces of the internal and external condyles, and was there firmly fixed. While the patient was under the influence of the anæsthetic the dislocation was easily reduced by manipulation and the movements of the limb were completely restored. Probably a portion of the ligament of the patella was separated from the bone, but this could not be ascertained by palpation through the integuments; there was no evidence of rupture of the tendon of the quadriceps extensor muscle.

Remarks by Dr. NEWMAN.—The case above described is exactly the converse of the one now published by Dr. Henry Rutherfurd. In the very interesting case brought forward by him the apex of the bone was thrown forwards, so that the articular surface looked downwards, while the base of the patella was wedged between the head of the tibia and the condyles of the femur. In my case it was the lower border of the patella that was fixed in the knee-joint; the articular surface looked upwards while its base projected forwards.

CASE 2 *Downward dislocation of the patella.*—A youth, aged 18 years, was admitted to Ward 25 of the Glasgow Royal Infirmary on Jan 28th last with an injury to the left knee, and in the absence of Mr. H. E. Clark came under the care of Dr. Henry Rutherfurd. The history was that the night before the patient had struck his knee against a bogey or low truck which was standing in his way and had been thrown down by the violence of the impact. Dr. W. S. Findlay of Bellshill saw him and recognised the existence of a dislocation of the patella; on admission the joint was painful, fixed, and its capsule was distended. Dr. Rutherfurd examined the patient under chloroform, expecting to find rupture of the quadriceps or possibly fracture of the patella. No gap could be found in the continuity of the rectus tendon nor could any fragmentation of the patella be made out. A body apparently corresponding to that bone could be felt impacted between the femur and the tibia as if it had been turned through a right angle on its transverse axis. On the presumption that it was the lower edge that was presenting forwards an attempt was made to reduce it, but this was not effected even after emptying the joint by an incision through the vastus externus. In view of the unusual nature of the injury Dr. Rutherfurd thought that it was advisable to have the parts skiagraphed before proceeding further. This was done the same day by Mr. Brennan, electrician to the infirmary, and the print which he obtained confirmed the diagnosis (Fig. 2). The patella is seen with its articular surface turned downwards and engaged between the femur and the tibia. The ligamentum patellæ is seen tightly stretched.

On Jan. 30th (two and a half days after the injury) the patient was again put under chloroform and Dr. Rutherfurd proceeded to operate for reduction of the displacement. It being probable to his mind that there was a rupture of the quadriceps which would require suture he turned up a flap from below the anterior tubercle of the tibia, exposing the front of the joint to above the insertion of the rectus femoris. The tendon though ecchymosed presented no rupture and he was still unable to pull up the patella from its position between the bones. Accordingly the joint was cut into about a finger's breadth from the outer side of the patella, and passing in the finger the bare anterior surface of the patella could be felt and seen presenting upwards; with a hook it was now levered into place. The wound of the capsule was closed with a continuous suture of chromicised gut, and afterwards the skin flap was dealt with in like manner. The joint was carefully emptied of blood by pressure and a bulky dressing was applied; no splint was employed. A fortnight later the dressing was removed, when the joint was found to be of normal appearance; there was no gap above the patella and there was no tilting forwards of its upper edge, as is typical in rupture of the quadriceps. Within another week the patient was walking about the ward and on Feb. 22nd he was sent out. On the day after the operation there was a rise of temperature to 101° F. Whether this was due to absorption of extravasated blood or to a slight formation of stitch abscess is doubtful. Next night the temperature was 100° and thereafter it was regularly below the normal.

Remarks by Dr. RUTHERFURD.—So far as published records go this would seem to be a unique case. Apart from compound injuries, I am inclined to think that engagement of the patella between the bones entering into the formation of the knee is rare, yet it is only a few weeks since that I was told by my colleague, Dr. Newman, of the first case which is described above, but the interest of the case which I have described lies in its bearing on the generally accepted view as to the classification of dislocations of the patella. This may be taken as expressed by Stimson:[1] "Dislocations [of the patella] upwards and downwards should not, I think, have a place in the classification, since they are the secondary results of other lesions, rupture of the ligamentum patellæ or of the tendon of the quadriceps, which are to be deemed the principal and controlling ones." The same view is set forth by Stephen Smith in his edition of "Hamilton on Fractures and Dislocations"[2] and by Berger[3] who quotes Malgaigne, and before him Petit, as having enunciated the doctrine. It may seem difficult to distinguish between a tearing away of the patella from the insertion of the quadriceps and a rupture of the quadriceps itself, but I think that the distinction is valid. In the case which I describe the periosteum was stripped from the front of the patella and remained connected with the quadriceps, so that the extensor apparatus of the knee was virtually intact. Rupture of the quadriceps, even if it be held to have occurred, was certainly not the "principal and controlling lesion." The lesion here was due to direct violence, and the difference between its results to the extensor function of the knee and that resulting from a true rupture of the quadriceps is analogous to the difference in the functional results in fracture of the patella from direct and indirect violence. Judging from the statistics collected by Berger in the article referred to there are at least three points wherein rupture of the quadriceps differs from the injury which I have described—namely: (1) rupture of the quadriceps is an accident of advanced life—more than two-thirds of the cases were over 50 years of age; (2) it is almost invariably due to muscular action—in the one case out of 28 where it was ascribed to direct violence the patient was the subject of locomotor ataxy; and (3) the recovery (apart from the results of suture) is slow and in many cases markedly incomplete.

Medical Societies.

OPHTHALMOLOGICAL SOCIETY.

Study of Inflammatory Exudates into the Vitreous.—Paralysis of the Third Nerve with Unusual Complications.—Double Symmetrical Opacities of the Cornea.—Erythropsia.—Eye Injury due to Lightning in South Africa.—Exhibition of Cases and Specimens.

AN ordinary meeting of this society was held on June 13th, Mr. G. ANDERSON CRITCHETT, the President, being in the chair.

Dr. LESLIE BUCHANAN read a paper on Inflammatory Exudates into the Vitreous which was illustrated by lantern slides made from his preparations. He said that the exudation into the vitreous in cyclitis was, in the first instance, formed in the pars ciliaris retinæ, and more especially in the non-folded portion of it, but soon the folded portion, the fibrous stroma of the ciliary body, and the retina took part in the production of the inflammatory exudate. The exudate into the vitreous body was seen in the fresh specimen fixed in 5 per cent formalin as opaque white flocculent masses. It might be divided into zones, which from the ciliary body inwards were as follows—namely: (1) a fibrous zone; (2) a fibrinous zone; and (3) a fibrino-cellular zone. The formation of fibrous tissue began very early, probably about the eighth day. The formation of fibrous tissue was accomplished by the action of certain ova nuclei on the fibrin ending in the formation of fibrous tissue. The cells which formed the exudate at first formed masses on the non-pigmented layers of the pars ciliaris retinæ and were of various characters. That these cells were not all derived from the endothelium was shown by bleaching and re-staining, when many cells might be seen migrating through the pigment layer to the free surface. In the retina also there was evidence of migration. The cells thus exuded passed to a greater or less depth into the vitreous. Here they proliferated rapidly. In the more superficial portions of the exudate degenerated protoplasm might be seen not having a nucleus, though no instance of mitosis had been seen. Fatty degeneration followed and further migration of nuclei took place, these finding their way back by the lymphatics. A fibrinous cyclitic membrane was thus left infiltrated with fat and highly vascular. The fat was absorbed, the blood-vessels were gradually constricted, leaving a comparatively avascular fibrous tissue layer, by the contraction of which the eye was distorted and destroyed. A further change was the formation of true bone. Spherical globules were formed, which grew, forming a solid mass penetrated by blood-vessels, and finally converted into bone. The bone corpuscles were probably fibrous tissue corpuscles. The cavities of the bone were lined by osteoblasts containing blood-vessels, fat, and crystals of fatty acids.

Mr. P. H. MULES reported a case of Paralysis of the Third Nerve with Unusual Complications. The patient was a man, aged 75 years, who, feeling ill on May 4th, 1900, proceeded to treat himself on the following original plan. He first took half a box of "wind pills," together with a variety of other sorts. Feeling no better he took two ounces of a solution of tartar emetic. The vomiting having ceased two days later, and feeling his head very sore, he applied to his forehead and scalp various applications chiefly used for veterinary purposes. He became so much worse that Mr. Mules was sent for. Incisions were then made into the œdematous scalp and 10 grains of calomel were given. The following day (May 10th) the patient was better, though sloughs covered the scalp and there was severe pain. It was then noticed that there was paralysis of the third nerve. On May 27th the scalp had healed but the paralysis remained. Mr. Mules thought that the cause of the trouble was herpes of the fifth nerve. This was the cause of the patient feeling ill in the first place. The vesicles were never seen on account of the applications which caused so much destruction of tissue. As a sequel to the herpes paralysis of the third nerve ensued.—Mr. DEVEREUX MARSHALL referred to an exhaustive paper on Herpes by Head and Campbell published last year in *Brain*. The cases were sometimes epidemic. The lesion was in the Gasserian ganglion.—Dr. ALDREN TURNER saw no reason why the third nerve should not be affected and did not consider motor paralysis uncommon after an attack of this disease.—Mr. MARCUS GUNN asked if there had been an injury and mentioned two cases in which an attack had definitely followed traumatism.—Mr. JOHNSON TAYLOR asked if any vesicles had been seen on the cornea.—Mr. MULES, in reply, stated that none had been observed.

Mr. MULES recounted a case of Double Symmetrical Opacities of the Cornea. The patient, who was aged 70 years, developed opacities of the cornea eight years ago. These were symmetrical and brownish in colour and had been increasing. The apices were at the pupils and their bases at the corneal margin. A vertical slit was present in each. One was removed by scraping but the other was removed far more easily by means of a fine knife inserted beneath it. The result was quite satisfactory.—The PRESIDENT said he had watched a similar case for seven years but it had not reached the pupil and he had done nothing to it at present.

Dr. W. H. R. RIVERS described a Form of Erythropsia which appeared after exposure to high illumination as a well-defined deep red border round a white object. The phenomenon might be regarded as an intermediate link connecting the ordinary forms of erythropsia with the transient red border seen round a white object which had been described by Shelford Bidwell. It was shown that Bidwell's phenomenon, "border erythropsia," the artificial erythropsia of Fuchs, and clinical erythropsia such as occurs after the removal of the lens, were probably closely related to one another. The causation of erythropsia in general was considered and reasons were given for believing that all forms were due to the colouration by the light stimulating the retina by blood, and this might be produced in several ways: (1) by transmission through the sclerotic, &c.; (2) by internal reflection from the lateral walls of the eyeball; and (3) by transmission through the anterior layers of the retina. The experiments of Birkhoff showed that erythropsia might occur when light was prevented from passing through the peripheral part of the eyeball, but these experiments did not exclude the third of the sources above-mentioned.—Remarks were made by Dr. F. W. EDRIDGE-GREEN and Mr. H. R. SWANZY.

Major M. T. YARR, R.A.M.C., gave an account of two cases of Eye Injury due to Lightning in South Africa. He stated that while encamped in the Orange River Colony in March, 1900, they were exposed to a violent thunderstorm. 1. Major H. had his tent-pole struck; at the same time he felt tingling down the right side of his head and right arm. He became partially unconscious but soon recovered, but the tingling persisted for some days. Four months later he discovered accidentally that he was practically blind in the right eye, and he was invalided to the base hospital. When seen by Major Yarr in August, 1900, he could only count fingers at three feet. There were several large hæmorrhages, evidently not of recent date, and patches of atrophy in the retina in the region between the superior and inferior temporal veins, with a few scattered and much smaller hæmorrhages in the periphery, some engorgement of the veins, pallor of the disc, and contraction of the arteries. The left eye was normal. 2. R. C., aged 25 years, a private in the 2nd Royal Berkshire Regiment, was employed on telephone duties at Belfast, Transvaal. On Oct. 18th, 1900, he was sitting at his "operating table" during a storm, when his instrument was struck by lightning. He fell, and on regaining consciousness he was unable to see. He had suffered no bodily injury but his instrument was bent. The next day he could distinguish between light and dark; about a week later he had perception of light in both eyes, could count fingers with the left, and the tension was normal. There was a large retinal detachment in the right eye, running in wavy whitish lines inferiorly. The left eye also showed a large detachment but spread over a wider area. The vision had previously been quite good.

The following cases and card specimens were shown:—

Dr. A. BRONNER: Growth of the Conjunctiva from an Old Man.

Dr. A. A. HUDSON: An Apparatus for Performing Massage on the Eyes by means of a Vibrating Hammer.

Major H. E. DRAKE-BROCKMAN, I.M.S.: A New Eye Speculum.

Mr. J. H. FISHER: Sub-retinal Cystic Swelling in the Centre of the Fundus.

Mr. INGLIS TAYLOR: Tubercle of the Iris.

Mr. RICHARDSON CROSS: Congenital Fibro-vascular Tumour Removed from the eye.

Mr. STANFORD MORTON: Double Coloboma of the Lens.

Mr. R. W. DOYNE: Hole in the Retina.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on June 7th, Dr. F. Schacht, the President, being in the chair.—Several new members were nominated.—Dr. E. A. Saunders showed two cases of Cretinism. One patient was a little girl, aged six years, who had been under thyroid treatment for two years; the second was a boy, aged nine years, who had been only under treatment for three and a half months. The girl first came under his care at the age of four years and then presented the typical appearance of a cretin. She was two feet six inches in height and weighed one stone 11 pounds. She could walk but a few yards and could only say two words. Her face was swollen and heavy, her nose was broad, she had a protuberant tongue, pouting lips, swollen abdomen, dry skin, and sparse hair. The thyroid gland could not be felt. She was placed upon thyroid gland, one grain three times daily, and had been kept on this dose since. She had steadily improved. The child could now walk, run, talk freely, and was generally bright and intelligent. Her growth was remarkable. In the first year after treatment she grew seven inches and in the second year four and a half inches, and had now attained her normal height. The boy, who had the appearance of being about four years old, was in reality nine and a half years old. In the three months he had been under treatment he had grown one and a half inches and had become brighter and more intelligent. He still, however, had the typical appearance of a cretin, but in addition had an excessive rigidity of the muscles of the legs and an increased knee-jerk.—Dr. Leonard Dobson described a case of a child, aged two years, who had all the typical signs of a cretin but was improving remarkably under one grain doses of thyroid gland daily.—Mr. C. R. B Keetley thought that there were many cases of the cretinoid state undetected. He noticed a child in his orthopædic department whom he gave thyroid extract to with great improvement in the symptoms.—Dr. Buttar asked whether the treatment must be continued for life.—Dr. Saunders considered that treatment must be continued at least during the stage of growth, and in the majority of cases probably for life, although in some cases the treatment might be omitted from time to time.—Mr. McAdam Eccles showed a case of Spina Bifida and Hydrocephalus after operation. The patient was a male child, born in December, 1900, and at birth a large tumour three inches by two and a half inches was discovered over the lumbar vertebræ; it fluctuated and was covered with a thin bluish semi-translucent membrane and was distinctly bilobed. The child thrived and in about a month Dr. Stanley Melville, under whose care he was, reported that the tumour seemed to be undergoing spontaneous cure. About Feb. 3rd the tumour rapidly increased in size and at the same time there was some bulging of the fontanelles and separation of the cranial sutures. This steadily increased, although at times it was relieved by a discharge of clear fluid from the ear. The child was admitted into hospital in April when the movements of his arms were normal but there was some paralysis of the lower extremities. There was evident fluctuation between the cranial and spinal swelling. In order to determine whether the fluid was intra- or extra-ventricular Mr. Eccles made an incision over the left posterior lateral fontanelle and entered the subarachnoid space, but little fluid escaped. A trocar and cannula were introduced into the left lateral ventricle and a large quantity (10 ounces) of fluid immediately escaped, followed by collapse of the spinal tumour. The wound was then dressed and no bad symptoms followed. In three days the tumour and ventricles appeared to be as tense as ever and it was decided to attempt to create a permanent communication between the ventricular and subarachnoid spaces. Accordingly an incision was made over the right lower angle of the anterior fontanelle and the dura mater exposed and opened. A strand of horsehair of about 15 hairs, two inches long, tied at one end, was introduced by means of sinus forceps, the tied end of the drain being passed for an inch between the dura mater and brain substance and the free ends passed through the brain substance into the lateral ventricle. The incision in the dura mater was not closed, but the edges of the scalp were drawn together and sutured. The child had no symptoms after the operation. There had since been a steady diminution in the size of the head. On May 14th the *first* and second toes of the right foot were found to be ulcerated, and as there was no diminution in the size of the spina bifida it was punctured and the toes then improved. Mr. Eccles stated that in some cases a strand of fine catgut had been used, but this was too quickly absorbed, and in others a metal capillary tube, but this was, as a rule, followed by a fatal result.—Mr. Keetley suggested the probability of a blockage of the drainage channel by lymph and thought that the danger of a metal tube was more from the irritation and hardness of the metal than its permanency.—Mr. Eccles, in answer, said that he used horsehair as it appeared to him to be less irritating than metal. He knew of no case where a tube had remained in so long as the horsehair drain in the present case.—Dr. Ross Sinclair showed a man with an Anomalous Tumour of the Scalp. The man was aged 31 years, and on the upper and back part of the left parietal bone there was a horizontal groove, and another which ran downwards and backwards from the two former ones. When he depressed his head the space rapidly filled up with fluid and a large soft tumour appeared. When he resumed the upright position the swelling immediately disappeared. He had no symptoms and complained of nothing but an occasional feeling of pins and needles over the tumour. He had had no fits. There was a history of a fall when a few *months old*, but no notice was taken of it.—The President thought it remarkable that the change in intra cerebral pressure did not produce any symptoms.—Mr. Eccles said that this was probably a case of traumatic cephalhydrocele, the fluid probably being cerebro-spinal and coming from the subarachnoid space. The absence of any symptoms was remarkable. He did not think there would be any difficulty in closing the aperture by a plastic operation, but as there were no symptoms the operation seemed uncalled for.—Mr. Keetley agreed with Mr. Eccles's opinion of the case. He had never seen anything like it before.—Dr. Campbell Pope showed a case of Venous and Lymphoid Swelling of the Cheeks in a boy aged 12 years. It appeared suddenly after scarlet fever seven years ago. The cheeks were swollen, thickened, and of a bluish tint. The swelling was greater in cold weather. No suggestions could be given as to treatment, but it was possible that electrolysis might be beneficial.—Dr. Saunders thought that it was probably a nævoid condition, in which both veins and lymphatics were involved. It was a most remarkable case.—Dr. Pope also showed a man, aged 36 years, suffering from Abdominal Aneurysm, probably of the splenic branch from the aorta. The patient had suffered severely from membranous colitis for five years and to ease his pain had been accustomed to lean across a deal table, pressing the abdomen hard against the wood. There was some history of syphilis. He could not now lie down because of the pain and pulsation.—Dr. Saunders asked the nature of the man's work.—Dr. Pope, in reply, said that the patient was originally sergeant-instructor of gymnastics in the army but had lately been engaged in laundry work. He had lost weight greatly. Olive oil in half-ounce doses had been of most service in treatment of the colitis. He could not take iodide of potassium as it increased his pain.

Otological Society of the United Kingdom.—A meeting of this society was held on June 10th, Sir W. B. Dalby, the President, being in the chair.—Mr. W. C. Bull showed a patient upon whom the complete Mastoid Operation had been performed followed by Skin-grafting. The hearing power had improved immensely after operation.—The President, Mr. Cheatle, and Mr. Ballance discussed the case.—Mr. R. Lake showed a case of Post-operative Atresia of the Meatus in an adult.—Mr. Baber referred to a similar case where he had performed Stacke's operation.—Dr. H. Tilley asked for any suggestions as to how to avoid post-operative meatal atresia.—Mr. Ballance referred to a case where he had drawn the pinna forward and removed a portion of the postero-superior bony wall of the meatus, cutting away also a considerable portion of the thickened cartilaginous meatus. Subsequently the raw surfaces were grafted with satisfactory results.—Dr. Dundas Grant thought that in such cases epithelial grafting might prove useful.—Dr. StClair Thomson showed a female patient in whom an Acute Mastoiditis had been cured by the employment of a Stacke-like operation.—Dr. Milligan considered that the case was not one of primary mastoiditis but of chronic disease with an acute exacerbation.—Dr. Dundas Grant concurred in this view.—Mr. A. H. Cheatle showed a case of Tuberculosis of the Temporal Bone in an adult.—The case was discussed by Dr. Milligan, Dr. Urban Pritchard, Dr. McKenzie Johnston, Mr. Ballance, Mr. Lake, and Dr. Jobson Horne.—Mr. Secker Walker read the notes of a case of Septic Thrombosis of the Lateral Sinus, Mastoid Disease, and Post-pharyngeal Abscess followed by recovery after extensive operative interference. A portion of the cochlea had come away as a sequestrum, but a fair amount of hearing was still retained upon the affected side.—The President and Dr. Pritchard discussed the case.—Dr. Adolph Bronner showed microscopical sections of two cases of Epithelioma of the External Auditory Meatus.—Dr. Milligan gave details of a case of Fatal Hæmorrhage from the Ear occurring in a child, aged two and a half years. The internal carotid artery was eroded externally to the temporal bone and was lying in an abscess cavity which communicated with the external auditory meatus. The common carotid artery upon the same side had been successfully tied by Mr. H. Lund. Death took place, however, two days subsequently from profuse arterial hæmorrhage.—Dr. Pritchard read the notes of a case of Temporary Loss of Audition and Equilibrium from an Overdose of Quinine.—The case was discussed by Dr. Barkan (San Fransisco) and Dr. Dundas Grant.—Mr L. A. Lawrence showed specimens of a Red Vegetable Growth removed from the External Auditory Meatus.—Mr. Macleod Yearsley showed macro- and microphotographs of a case of Papilloma of the Auricle.—Mr.

W. C. Bull showed a specimen of Central Necrosis of a Portion of the Semicircular Canals.—Mr. C. H. Fagge showed a specimen of an Exfoliated Cochlea.

Reviews and Notices of Books.

An Introduction to Physiology. By WILLIAM TOWNSEND PORTER, M.D., Associate Professor of Physiology in the Harvard Medical School. Cambridge, Mass.: The University Press. 1901. Pp. 314.

FEW will question that the substitution of practical exercises in the place of mere book study has proved of immense value in education. In physics, in chemistry, in anatomy, in botany, every experienced teacher and examiner knows well the difference between the student who has painfully committed his subject to memory from some text-book and him who has acquired his knowledge in the laboratory, the field, or the dissecting-room. The present work is intended as a guide to the young physiologist. The idea of making the student perform the simpler experiments of physiology for himself is not new; various treatises, such as the Handbook of Physiology by Several Authors, the Practical Physiology of Foster and Langley, the Manual for the Physiological Laboratory of Harris and Power, the Physiology, Experimental and Descriptive, of Cotton, and others, all have the same object in view. The difference in the value of these works is the manner in which the instruction is given. Dr. Porter has placed before the student a series of exercises which if he carries out with his own hands will supply him with the key to physiological inquiry, or, in other words, will furnish him with all its fundamental data.

The subject-matter of the first part of the book is the behaviour of nerve and muscle under the influence of stimuli that can be applied by the student with comparatively simple and very inexpensive apparatus. Naturally the author begins by giving directions as to the method to be adopted in making a nerve-muscle preparation and a short account of the instruments which are required. The effects of the electric stimulation of muscle and nerve by the continuous and the interrupted current are well given and this is followed by a section on chemical and mechanical stimulation. Irritability and conductivity are then discussed, which is again followed by the electromotor phenomena of muscle and nerve. The second part of the book is occupied with the consideration of the mechanics of the circulation and the innervation of the heart and blood-vessels. Both parts are divided into short chapters or sections each of which is devoted to a particular experiment, and the student is led on by easy steps from the more simple to the more difficult physiological experiments. In the earlier experiments described the independent irritability of muscle is shown by instructing him in the mode of obtaining a nerve-free muscle—a muscle with degenerated nerve—and by paralysing the nerve-endings with curare. Then other experiments show that irritability and contractility are separate properties of nerve; that the specific irritability of nerve is greater than that of muscle; that the same nerve may conduct impulses both centripetally and centrifugally, and so on. At the close of each section the instruments and apparatus required for the demonstration are shortly given, as, for example, for the experiments just referred to the following are mentioned: normal saline solution, bowl, towel, pipette, glass plate, dry cell, inductorium, key, wires, frog with sciatic nerve degenerated, and more than 20 other articles. A great saving of time and temper is thus effected; everything being at hand there is no interruption to run after a piece of string or a muscle clamp, or some trifle without which the experiment is apt to fail. The part devoted to the mechanics of the circulation contains a description of a simple artificial scheme, and gives, besides other information, experiments explanatory of blood-pressure, the characters of the cardiac muscle, the heart-sounds, the pulse, and the chief phenomena of cardiac stimulation and inhibition. Many, if not all, of these experiments can be performed by a student of very limited means, a kymograph and an inductorium being perhaps the most expensive of the instruments required. In conclusion, we must congratulate Dr. Porter on the clear exposition which he has given of the fundamental experiments of physiology, and we sincerely trust that his work will receive encouragement from the teachers of physiology in this country.

Aphorisms, Definitions, Reflections, and Paradoxes, Medical, Surgical, and Dietetic. By A. RABAGLIATI, M.A., M.D., F.R.C.S. Edin. London: Baillière, Tindall, and Cox. 308 pp. Price 7s. 6d. net.

THE existence of this book is due to Dr. Rabagliati's conviction that in the realms of medicine and surgery we have collected a large number of observed facts and have insufficiently exercised our reason upon them. The writer is of opinion that the time has come to formulate a philosophy of medicine, to generalise upon a large number of careful observations. His book is intended to be "a preface to the study of the theory and art of medicine," and it is intended also to remedy confusion of nomenclature and to "obviate conflicts of opinion and practice" among even the most distinguished exponents of the arts of medicine and surgery. We do not admit the author's premiss that there is little use in further observation as compared with the use in drawing general deductions on which to found principles of practice, nor can we admit that there has been, generally speaking, a deficiency of theorising on the part of medical writers as compared with a relation of observed facts. Supposing, however, that we granted the utility of sweeping generalisations in medicine and surgery, subjects which from the varying and human nature of their objects of study admit very little of generalisation, we should find not much to extol in the execution of the task in the book before us. There is an unfortunate profusion of verbiage in Dr. Rabagliati's work, a tedious amount of repetition, a very limited view, and some remarkably incorrect statements. As regards the confusion of nomenclature that is to be removed for us what confidence can we place in an author who devotes several pages to the demonstration of the superiority of his new term *initis* in place of the old "rheumatism" when he gives no clear idea of exactly what affections the word is to express, or how can we hope for simplicity and clearness in the doctrines of a writer whose pages teem with "poly- and pollaki-siteism" and such remarks as this—"This overgrown or hypertrophied tissue is very labile and easily breaks down with excessive combustion or oxidation."

The only idea of real worth that we have been able to extract from the book is the familiar one that disease is largely due to unwise feeding. The deduction that Dr. Rabagliati is constantly arriving at is that poly-pollaki and kako siteism or -potism are to blame for any disorder to which he is alluding. Some of the cases which he quotes in support of his contention are so remarkable and so directly opposed to the common experience that the author would have been wise to have given them in greater detail. Dr. Rabagliati's views on the causation of disease, from cancer to corns, is that all are due to mistakes in the nature or quantity of food. He has cured dysmenorrhœa by restriction of diet and would equally have routed carcinoma had the cases met him earlier; anæmia of all kinds is a matter of overfeeding, and the specific fevers are set up by inflammations due to too free ingestion. The aphorisms in this work are obvious, the definitions futile, and the reflections involved.

The Commonwealth of Cells. By H. G. F. SPURRELL, B.A. Oxon. London: Baillière, Tindall, and Cox. 1901. Pp 126. 67 Illustrations. Crown 8vo. Price 2*s.* 6*d.*

THOSE who have read Verworn's General Physiology will appreciate the title which Mr. Spurrell has chosen for his collection of essays on the problems of the human organism, for the central idea of that masterly work has been the elaboration of the conception of the human body as an aggregation of cell-units working together for the common weal under the administration of the nervous system. Mr. Spurrell's task has been to simplify this philosophical conception to the level of intelligence possessed by that ever-increasing section of the public which takes a keen interest in the workings of the body and the material basis of the mind. That this task has been completed without the aid of technical expressions and strictly scientific nomenclature reflects the greatest credit on the author's ingenuity. The class of readers to whom these essays will more particularly appeal will be students of philosophy and of branches of natural science other than physiology. The story of the human body as unfolded in these pages reads rather as a romance than a tale of dry bones and hard facts, for the author has an enviable facility of expression and a happy knack of appealing to the imagination of his readers. Since the time of Huxley's Physiology it is probable that nothing has been written which is so likely to popularise this fascinating branch of science as this series of essays by Mr. Spurrell. When Huxley wrote his monumental text-book the science of physiology was in its infancy and, to make use of an Irishism, was more anatomical than physiological. To-day physiology is brimful of the most intensely interesting applications of chemistry. Structure, both microscopic and macroscopic, is but the alphabet which enables us to understand the really interesting problems of life. It is these latter problems rather, the A B C of the science, which are dealt with in these pages. Mr. Spurrell is eminently up to date and his essays contain references to many important discoveries only recently published, and, further, the chemical basis of protoplasmic activity is reduced to the simplest terms so far known to science, but the process of reduction is led up to by such gradual and easy stages that the reader is unconsciously introduced to problems which have but recently defied solution.

It is not too much to say that no intelligent and educated person can read these pages without considerable profit. Those who possess previous knowledge of physiology will find their views all the clearer and those who possess no such knowledge will appreciate this lucid introduction to the subject. It will in no way weaken our praise of this charming little collection of essays if we point out that on page 30 it is incorrectly stated that "the distressing symptoms of goitre supervene on the surgical removal of the thyroid gland"

LIBRARY TABLE.

Atlas und Grundriss der Traumatischen Fracturen und Luxationen. (Atlas and Elements of Traumatic Fractures and Dislocations.) By Professor Dr. H HELFERICH of Kiel. With 79 Plates and 158 Figures in the Text by B. KEILITZ (Artist). Fifth revised and enlarged Edition. Munich: J. F. Lehmann. 1901. Pp. 338. Price 12 marks.—As this is the fifth edition of this well-known work it is very evident that it has been largely appreciated, and even two English versions of it have appeared. In the present edition nine Roentgen-ray skiagrams and 21 illustrations in the text have been added to the already large number. The author, however, has been careful, as he tells us in his preface, to deal briefly with all the rarer fractures and dislocations so as to maintain the elementary character of the work. The difficulty of interpreting the products of the Roentgen rays has induced Dr. Helferich to have taken some skiagrams of normal joints, and Dr. Werner prepared from these some explanatory diagrams which serve to make as clear as possible the normal relations of the bones as "projected" on a sensitive plate. In some points we are inclined to think that this volume is the most successful of a very excellent series.

The Treatment of Fractures. By CHARLES LOCKE SCUDDER, M.D., assistant in clinical and operative surgery, Harvard University Medical School, assisted by FREDERIC J. COTTON, M D. Second edition, revised. With 611 Illustrations. London and Philadelphia: W. B. Saunders and Co. 1901. Pp. 460. Price 19*s.* net —The most striking characteristic of this work is the profusion of illustrations, for they are more than 600 in number, although there are only 460 pages of text. No small proportion of the illustrations consists of diagrams representing fractures and the methods of applying splints, and these are so clear that it would be difficult indeed, for anyone to misunderstand the treatment advocated. Every point that could possibly be represented graphically has its illustration. An example will serve to show the thoroughness with which this has been done; in the chapter on Fracture of the Vertebræ there are 29 illustrations; 11 of these represent the bony lesions; four illustrate the damage to the spinal cord; four represent the normal anatomy of the spine, the cord, and the spinal nerves; two show how to examine the cervical vertebræ for fracture, by means of a finger introduced into the pharynx; seven are diagrams indicating the area of anæsthesia in spinal fracture; and the remainder illustrate the attitude of the patients. There is really very little that needs to be said as to the details of the work, for it is uniformly good. The author speaks very highly of Cabot's wire splint, which is but little known in this country—certainly not so well known as it deserves to be. The plaster-splint is recommended also, but the plaster-of-Paris roller appears to be the form chiefly employed. A very valuable chapter is that devoted to the interpretation of Roentgen-ray pictures. It is written by Dr. E. A. Codman and puts very clearly the difficulties which there are in understanding exactly what is seen in a skiagram. The practical value in fracture of the x rays is well described and the writer shows that we now know much more about many fractures—for instance, it is recognised that the styloid process of the ulna is fractured in a very large proportion of cases of Colles's fracture, some say in as many as 80 per cent. The question of danger from the x rays is discussed, and some experiments of Professor Elihu Thomson on himself are recorded by which he caused severe inflammation of a finger; the conclusion is arrived at that the skin should never be less than 12 inches from the Crookes's tube and that the exposure must not be too prolonged. A useful bibliography of the recent literature of fracture is appended to the volume.

Annals of Ophthalmology. H. V. WÜRDEMANN, M.D., Managing Editor. January, 1901. No. 1. St. Louis, Mo.: Jones H. Parker. Price 18*s.* per annum. Published quarterly.—A large portion of the annals is occupied with reveiws and abstracts of papers and memoirs that have appeared in other journals, but there are several original articles. Amongst these is one on the Bacteriology of the Conjunctival Sac and its Bearing upon Surgical Procedure, by Dr. P. Chalmers Jameson of Brooklyn, N.Y. The bacteria found in the sac, of which pure cultures were made by Dr. Jameson, were the staphylococcus pyogenes aureus, staphylococcus pyogenes albus, staphylococcus epidermis albus, aerobacillus citreus, xerosis bacillus, bacillus coli communis, and bacillus subtilis. These occurred in greatly varying frequency in different cases and under normal conditions do not propagate, the eye under ordinary circumstances being possessed of the means of antagonising bacterial growth. Dr. William Posey of Philadelphia and Dr. Edward Shumway describe a case of Alveolar Sarcoma of the Choroid. Dr. Edward Jackson of Denver, Colorado, in a short article shows that homatropin is a very reliable cycloplegic. Dr. L. Webster Fox of Philadelphia, Pa., recommends grattage of the conjunctiva for troublesome cases of spring catarrh. Dr. Carl Schulin of Helena, Mont., advocates the view that myopia and astigmatism are induced by the pressure of the lids and the conditions present during sleep; and lastly, there is an article by Dr. M. F. Weymann of St. Joseph, Mo., on Contusions of the Eye.

Archives of the Rœntgen Ray. Vol. V., Nos. 1 and 2 London: Rebman, Limited. August, 1900, and January, 1901. Price 4*s.* each number.—The first of these numbers contains an interesting paper by Dr. R. N. Wolfenden and Dr. F. W. Forbes Ross on the Effects produced in Cultures of Micro-organisms, including Tubercle Bacilli, by Exposure to the Influence of an X-Ray Tube. The authors discuss the various factors which may possibly influence their growth, such as (1) the x rays, (2) the cathodal rays, (3) the disturbance of the electric field, and (4) the production of ozone, increase of temperature, &c. They sum up their conclusions as follows. It is impossible by any ordinary long exposure or exposure to a high vacuum tube to kill growths of bacilli or cocci, the apparent death in cultures so treated being due to exhaustion of vitality from excessive proliferation. These observations appear to be at direct variance with the results which are being universally obtained in the treatment of lupus with the x rays. A new apparatus for localisation is described by Dr. Rémy of Paris, with very good illustrations of the method of using the instrument. Mr. James Wimshurst, F.R S , communicates a very full account of the development of his Influence Machine. This number also contains the President's Valedictory Address. The skiagrams at the end of the number are very good. Dr. Hugh Walsham contributes two skiagrams of Renal Calculi before and after the Removal of the Kidney. The second case is instructive as showing that we may be deceived as to the number of stones shown on the plate taken before operation. In this case the shadow of three stones are distinctly seen, but on taking a skiagram of the kidney after removal numerous stones are shown varying in size from a small bean to a pin's head. This is the first instance we have seen of a kidney with calculi radiographed after removal from the body. Staff-Surgeon Bassett Smith gives a good skiagram of Fracture of Both Clavicles. The second number contains the opening address of the new President, Dr. John Macintyre of Glasgow, in which he reviews the Progress of the Science during the Past Year. Mr. Mackenzie Davidson gives a clear description of his very ingenious Stereoscopic Fluoroscope and Rotary Contact Breaker. Some very good skiagrams, mostly of bone disease, complete the number.

Golden Rules of Aural and Nasal Practice. By PHILIP R. W. DE SANTI, F.R.C S. Eng., senior surgeon to outpatients, aural surgeon and lecturer on minor surgery and aural surgery, Westminster Hospital. Bristol: F. Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Pp. 87. Price 1*s.*—Mr. de Santi has issued under the above title a short synopsis of these subjects. Of the two the nasal rules are the better, though not the more complete. The aural half contains some evidences of carelessness which do not enhance the value of the book—as that the ear-drum is divided into two quadrants, and that the surgeon should syringe along the upper or lower wall of the meatus instead of upper and posterior. Neither of these is quite a golden rule. To students who are anxious to obtain rapidly some information the book will be a distinct aid.

Burdett's Hospitals and Charities, 1901. By Sir HENRY BURDETT, K C B. London: The Scientific Press. Price 5*s.* Pp. 1050 —This is the twelfth issue of Sir Henry Burdett's invaluable compilation and we really can say nothing new about the book, except that it is some 100 pages larger than its immediate predecessor. For information about hospitals, nursing homes, charities, hospital finance, convalescent homes *et hoc genus omne* there is but little known which cannot be found in "Burdett." He is the Whitaker of hospitals. We are glad to see a warning on p. 176 against the wiles of "professional philanthropists." The heart-rending appeals of these gentry must be familiar to all our readers, who probably know how to appraise them at their true value, but evidently some are still deceived, and to these Sir Henry Burdett's warning may be useful.

Helwân and the Egyptian Desert. By W. PAGE MAY, M D. Lond., &c , with articles by Professor SAYCE and Professor SCHWEINFURTH. London: George Allan. 1901. Pp. 110. Price 3*s* —This is an excellent little book and much above the ordinary type of health-resort guide. Its three chief sections are (1) that on the Archæology of Helwân and the District by Professor Sayce, a most interesting and instructive article; (2) that on the Flora of the Desert and a Description of Desert Conditions in Regard to Floral Life by Professor Schweinfurth; and (3) that on the Special Advantages of Helwân as a Health resort in Winter. But the little volume contains much information also in reference to the amusements and sights of Cairo, is embellished with numerous and excellent photographs, and contains detailed information as to the different routes to Egypt and their respective advantages or disadvantages. It has also numerous tables of meteorological observations which no one is likely to read although their results are undoubtedly interesting and important. It is evident that Helwân is very well suited to become a favourite health-resort and also a winter resort for the healthy who are content to lead a quiet, wholesome life amid the remains of a remote but fascinating civilisation. In any case this book is to be recommended as one containing much reliable information in reference to the climatic winter conditions in Egypt generally and may be useful in helping intending visitors to make up their minds whether to go further south or to be content with a sojourn in what is undoubtedly the most accessible health-resort in Egypt.

ROYAL INSTITUTE OF PUBLIC HEALTH.—The provisional programme of the arrangements of the congress of the Royal Institute of Public Health, which will be held at Eastbourne from July 25th to 30th, has just been issued. The railway companies will issue return tickets to Eastbourne to delegates at a fare and a quarter, but to obtain these special tickets a form, which will be sent by the honorary secretaries, must be presented at the booking-office by those attending the congress. The London, Brighton, and South Coast Railway will issue return tickets from Eastbourne to neighbouring places to delegates at a fare and a quarter during the congress. Drives will be organised to various places of interest in the town and neighbourhood, and visits will be made in connexion with sanitary matters, drainage, &c. Special facilities are being arranged fo [illegible] th entrance to Devonshire Park, [illegible] bs in Eastbourne, the Royal Eastb [illegible] Golf Clubs, the Eastbourne Cricket and Football Club, the Upperton Lawn Tennis Club, the Compton Croquet and other clubs. A special guide-book (with maps) is also being prepared for delegates.

THE LANCET.

LONDON: SATURDAY, JUNE 22, 1901.

The Meeting of the General Medical Council.

CONSIDERING the number and the delicacy of the questions which had to be discussed by the General Medical Council, we congratulate it upon the fact that its late meeting lasted only seven days, instead of eight or nine as did the two immediately preceding sessions. By common consent, all the more striking for being unexpressed, the subject of the registration of midwives was ignored. The reputation of the Council will in future turn very much on the way in which it can arrange its business and clear its programme of recurring questions. If it were not for two or three subjects which seem to fascinate the Council perennially, and to give occasion for endless discussion, there would be no reason that we can see why the session should cover more than five or six days, which would be the simplest and most creditable solution of its financial difficulties. At the same time it must be remembered that to ignore a question is not to settle it. What is required is progress. The best thing the Council can do is to come to right decisions, and the worst is to talk without coming to any decisions at all. The attempt to save time in the recent meeting was most evident in the arrangement of business and in bringing on the disciplinary work of the Council on the second instead of the third day of the session, and we welcome with pleasure evidence of a growing sense of the discredit accruing to the Council from fruitless discussions handed on hopelessly from one session to another.

There were two great questions before the Council this summer by the handling of which it will be very much judged, and in our opinion the Council cannot be wholly congratulated on its attitude in either case. The first of these questions was the serious difference between the English Royal Colleges and the General Medical Council with reference to the recognition of schools for the teaching of the preliminary sciences—chemistry, physics, and biology. This is now the third year in which the Council has had this most important subject before it. Some notion of the depth to which discord has reached may be got by considering that the Royal Colleges now no longer require candidates for their diplomas to be registered as medical students by the General Medical Council, though all parties in the Council, including distinguished Fellows of the Royal Colleges, regard such registration as a chief instrument in the Council's hands for controlling the preliminary education of the profession. It is not contended on either side that the Council has the power to enforce the registration of medical students, but all agree that registration has been very beneficial and that the action of the Royal Colleges in abandoning it deals a serious blow at the authority of the Council and its influence over education through registration. The risk to the system of registration brought about by the new regulations of the Royal Colleges, which no longer require registration of their students, has put into the shade the original difference between the Colleges and the Council. This new development of the dispute excited far more feeling in the Council than did the original question as to the right of the Council to dictate to the Colleges as to the bodies from which teaching in science should be accepted. But the question must be considered in its original form—Has the General Medical Council the right to demand that before recognising institutions for teaching science the Colleges shall see that they are *approved* by the General Medical Council? Which side is to blame for the complete *impasse* now reached is another point. The Colleges, ignoring the demand of the General Medical Council and its system of registration, acted, as they allege, in discharge of a function and a responsibility imposed on them by charter: the General Medical Council acted without the support of law, but with the moral authority of a council of medical education. The Council, we think, should have come to a decision, and the majority of its members expected the matter to be faced. It seemed probable at one time that a practical settlement would be reached. And here we have to recognise a new force in the Council in the person of Dr. NORMAN MOORE, whose familiarity with the facts of scientific teaching in general schools as well as with the facts affecting the efficiency of such teaching in medical schools and universities was made obvious directly he took part in the debate. Dr. NORMAN MOORE'S speeches, especially the speech of Saturday, June 8th, made a great impression on members of the Council, even on many, such as Sir CHRISTOPHER NIXON, who have always stoutly opposed the view of the Royal Colleges, chiefly on the ground that they were endangering the five years of the medical curriculum. Dr. NORMAN MOORE made it clear that the Colleges had never in one instance tampered with the requirement of the Council that five years should elapse from the time of registration as a medical student before qualification, and that this period should be spent in medical as distinguished from preliminary education. So strong was the impression thus produced that it went far to convince the Council that there was no practical difference between the objects of the Royal Colleges and those of the Council. The time seemed ripe for a resolution that would have conciliated both sides and led to a way out of the *impasse* when Dr. MCVAIL propounded a motion that the new regulations of the Royal Colleges, which had been supplied in full to the Council, "did not afford evidence that these courses of study were in all cases sufficient." He moved to this effect, the President ruled the motion to be in order, and Dr. MCVAIL only failed to carry it by two votes. The Council then contented itself with doing no more in the matter than sending to the Education Committee two proposals, of Dr. BRUCE and Mr. BALL respectively, for including chemistry, physics, and biology for the future in the subjects to be passed before the commencement of a four years' course of medical study. The complete *impasse* between the Royal Colleges and the Council remains and we have before us the prospect of interminable discussion on the subjects involved

But the most important subject with which the General Medical Council had to deal this summer was that of its own somewhat complicated finances In this matter it had sought *the advice of an expert, and the report of the* expert was in its hands a month before the meeting The great point brought out in that report was the existence of a tendency to such an annual excess of expenditure over income—amounting last year to £1037 11*s* 1*d*—as to involve the gradual diminution of the surpluses of the Branch Councils funds and perhaps their extinction, as in the case of the Irish Branch Council The expert recommended practically two things—first, that the distinction between the Council and its Branches for financial purposes should be disregarded, and secondly, that the fees of the members of the Council should be reduced Though some of the members think seriously of the finances of the Council none of them mentioned the suggestion of the expert that the fees should be reduced The only thing done by the Council was to refer the matter to a new committee with a curious special suggestion "to consider what amendments, if any, are necessary in the Medical Acts in order that the relations between the Council and its branches may be readjusted and the financial position of the Council placed on a satisfactory basis" This resolution does not, we hope, represent the mind of the Council, for it indefinitely postpones the financial adjustment which might easily be achieved We think that the Council failed grievously to set a good professional example of the respect due to an expert, for they not only did not follow the opinion of their financial adviser, but they did not even discuss it

Medical Defence and Protection.

THE annual reports of the Medical Defence Union and of the London and Counties Medical Protection Society for 1900 which have recently been received by us, are worthy of the attention not only of the subscribers to these bodies but of every practising member of the medical profession residing in Great Britain and Ireland We can but ask those practitioners who do not insure in any defence or protection society to reconsider their position and we may (to quote from the report of the Medical Defence Union) remind them that "no qualified member of the profession can with any certainty say that he is absolutely secure from attacks from unscrupulous persons however able his treatment of the cases involved may have been" The report goes on to say "These attacks are not confined to the practice of general practitioners; consultants of the highest position both in medicine and surgery have been obliged to ask the help of the Medical Defence Union in defending their professional honour from unjust and unjustifiable attempts to disparage it by charges of alleged malpraxis'

Opening with these important words of caution the Council of the Medical Defence Union proceed to show by various illustrative and interesting cases in what way those practitioners who have been attacked and have fortunately been members of the Union can be defended at the least possible trouble and anxiety to themselves personally and at no cost beyond the small subscription of 10*s* per annum. The report also touches upon other matters of interest dealt with during the past year, for instance, the Lunacy Act with all its attendant evils and dangers to the unsuspecting practitioner who may be induced "for the sake of gain" to take into his house as a resident patient one who, although mentally deficient, is not in his opinion and that of others "certifiable' and yet later finds himself summoned by the Treasury, acting on behalf of the Lunacy Commissioners, for penalties under the said Act Mr W E HEMPSON, the solicitor to the Union, in his particular section of the report draws special attention to the risks run under the Lunacy Act as at present constituted, and we cannot better point a moral and adorn a tale than by quoting the words which he uses "By Section 341 of the Lunacy Act, 1890, the word 'lunatic' is defined to mean 'an idiot or person of unsound mind' By Section 315 (1) of the same Act it is enacted as follows 'Every person who, except under the provisions of this Act, receives or detains a lunatic or alleged lunatic in an institution for lunatics, or for payment takes charge of, receives to board or lodge, or detains a lunatic or alleged lunatic in an unlicensed house, shall be guilty of a misdemeanour and in the latter case shall also be liable to a penalty not exceeding £50 Upon a strict construction of these two sections, therefore, any person who for payment takes charge of, or receives to board or lodge, or detains a lunatic or 'alleged lunatic' in an unlicensed house commits an offence within the meaning of the section That a lunatic is a person of unsound mind is a proposition which, I assume, may be accepted without discussion, but that every person who is of unsound mind is thereby to be pronounced a *lunatic* and *to be controlled and treated as* such is, in my opinion, a matter which was not contemplated in the Act nor intended to be enacted thereby The risk therefore is not confined to medical men, but would apply equally to the proprietor of an hotel or boarding-house" Mr HEMPSON suggests that further legislation is required to remove from the path of medical men a danger which, in his opinion, was never contemplated by the original act, and he suggests that an extension of the word "lunatic" to mean a person of unsound mind and medically certifiable as "a proper person to be taken charge of and detained under care and treatment" would solve the difficulty This proposal appears to be a sound one, and it behoves *those who are interested to take the* necessary steps to remove the existence of a danger both to the public and to the profession It appears from the report that the number of legal cases referred by the Council of the Union to the solicitor was 140, and that of these cases 49 were actions for libel and slander Of the remainder 26 involved the defence of members of the Union in actions either threatened or brought against them for *malpraxis*, 48 related to actions taken or defended in matters other than slanderous or libellous, and 17 cases were actions against unqualified practitioners or for the purpose of the suppression of such practice Some illustrative cases dealt with under the heading of "Libel and Slander" are given by the Council, and in each and every case the Union was victorious. The Council deplore the inability of recovering costs from persons who without means can yet, with the aid of speculative solicitors, move the ponderous wheels of the legal machinery, or, in other words, bring actions which must be defended at whatever cost to the Union.

The schedule of cases occupies as usual many pages of the report and is indicative of the varied matter which comes before the executive to be dealt with daily. The funds of the Union are again found ample to meet the annual expenditure—a loss of about £100 owing to the defalcations of a trusted clerk being covered, it is reported, by the policy of guarantee wisely taken out by the Council.

The London and Counties Medical Protection Society has not such a large roll of members as the Medical Defence Union, but has nevertheless performed excellent and useful work. Especial attention has been paid to the interests of the dental section, as was shown by the charges brought against certain dentists practising at Nottingham before the General Medical Council at the recent sessions, when the secretary of the society appeared to prosecute, and amply justified the course adopted by the society in bringing the matter of objectionable advertising before the Council. Unceasing efforts have also been made by the society to suppress unqualified practice, but unfortunately the highly unsatisfactory state of the law enables quacks to continue their evil practices with impunity. In no department of commercial enterprise can money be more easily obtained by false pretences than by quacks purporting to cure all diseases by inventions of their own, and it is very seldom that a conviction can be obtained in spite of repeated attempts on the part of the two bodies to whose reports we are referring. Drastic alterations in the present laws are needed, but the legislature shows no signs of protecting the public from some of the greatest swindlers of modern times. Unfortunately, it is precisely that class of the community which can least well afford it that is mainly victimised—namely, those who are dependent upon their daily work for their livelihood; the better educated are, as a rule, not so easily deceived. Little wonder is it, then, that the secretary of the London and Counties Medical Protection Society was obliged to state that the council of the society had not seen its way to carry out the prosecution of a quack during 1900. The society, however, will doubtless not diminish its endeavours to bring about an alteration in the existing laws, so that greater facilities will be given to lessen an evil which cannot be exaggerated.

In conclusion, we would strongly urge upon practitioners throughout the kingdom the importance of belonging to one or other of the two bodies whose work we have been referring to; by so doing the power of these associations will be greatly increased to the advantage not only of the individual members but of the profession in general.

◆

The British Congress on Tuberculosis.

THE British Congress on Tuberculosis, which will be held in London from Monday, July 22nd, to Friday, July 26th, is attracting widespread interest and attention. Numerous foreign delegates will be present to add their testimony to the value of the investigations which are everywhere being made into the methods of combating one of the most universally prevalent and fatal maladies and one which attacks man and beasts. Our knowledge of the nature of tuberculosis has made great strides during the last two decades, and an assemblage of scientific men met together with the simple purpose to set forth individual observations and to discuss the many diverse problems connected with the disease—to take stock of the state of opinion as regards the causes, pathology, treatment, and prevention of tuberculosis—cannot fail to be of the greatest benefit not only to individuals but to mankind in general.

The public are very quick to take up any new theory or method of "cure" of tuberculosis, especially the pulmonary variety, which may be introduced, and all the more if it be injudiciously lauded by the lay press. This unfortunately not infrequently happens, and therefore a congress of genuine investigators is of real importance as the proceedings will tend to set in their proper place the therapeutic measures which have not fulfilled the hopes at one time expressed for them, and to bring more into prominence those which extended experience has shown to be successful. The "open-air" treatment of tuberculosis will thus receive considerable attention and naturally the much-disputed influence of climate will be carefully discussed. There are certain aspects of tuberculosis which it is important that the laity should know something about. The words used by His Majesty the KING, then PRINCE OF WALES, in opening the International Congress of Hygiene in 1891 have become historical. "If preventable, then why not prevented?" This phrase is particularly applicable to tuberculosis, but the general public require to be educated before the necessary measures can be carried out by which, without undue interference with the "liberty of the subject," chances of infection may be reduced to a minimum. Twenty years ago heredity was considered one of the main etiological factors in tuberculosis. The discovery of the pathogenic bacillus by Professor KOCH greatly reduced the importance of heredity, and some authorities would seem to go so far as almost to discard it. This, however, is carrying bacteriological views to an extreme. The bacillus alone is obviously not the sole cause of the disease, otherwise the human species would long ago have become extinct. The exact nature of the second etiological factor (there may be several) we are not as yet acquainted with; certain terms are employed concerning it which are somewhat vague, such as "suitable pabulum" or "deficient resistance"; and probably heredity plays no inconsiderable part, although not so important a one as was originally thought, in conferring on the offspring of tuberculous parents a diminished power of resistance to the attacks of the bacillus. An overpowering predominance of opinion, however, points towards infection as the most powerful agent in the spread of the disease; and while the medical profession can do much towards lessening the mischief by observation of the habits of their patients and careful tuition, the carrying out of the hygienic instructions rests mainly with the sufferers themselves The open air establishments which have been, and are being, formed in various parts of the country serve not only as places where patients undergo treatment, but act as most valuable schools to educate those who might spread infection as to the measures they must adopt to prevent themselves from becoming objects of danger to their fellow creatures The conclusions arrived at by the members of the Congress will doubtless accentuate the importance of such institutions and will happily support the endeavours which are being made by public bodies and societies to spread the necessary information amongst all classes of the community A further use of congresses such as the one which is to meet in London next month is that the resolutions which they pass may lead to important representations being made to the Legislature There is ample scope for such in regard to tuberculosis, and the many important subjects to be discussed by the Veterinary Section and the State and Municipal Section of the British Congress on Tuberculosis may, we hope, lead to the introduction of certain obvious measures against the spread of tuberculosis both in man and animals

Annotations.

"Ne quid nimis"

THE ARMY MEDICAL SERVICE

THERE is still no news to report with regard to the intentions of the War Office The Secretary of State for War maintains his sphinx like attitude and the situation can perhaps best be described in the words of Jeames de la Pluche as "wropt in mystry" What possible benefit there can be to anybody in keeping up this mystery we are at a loss to understand and nobody seems to possess any sort of clue to the reasons which dictate the curious policy On one point all members of the profession whose views we have ascertained seem to be agreed—i e, that the course pursued by the War Office is not very complimentary either to the Army Medical Service in particular or to the profession in general Why cannot the name of the new Director General be announced? If it be that the appointment is to be held over until a committee has made inquiry and completed its report the delay would be at all events intelligible (though it might suggest some doubt as to the expediency of allowing Director General Jameson to retire at the present moment) We have excellent reason to believe that this committee of experts has already been constituted Why are not the names of its members made known to the public? We cannot understand the spirit of secrecy which prevails and we deprecate it very strongly At the dinner of the Royal Army Medical Corps on Monday evening last more than one speaker alluded to the want of sympathy that was shown in certain quarters with the Army Medical Service This want of sympathy and, we may add, of confidence, is only too well illustrated by the attitude adopted by Mr Brodrick who may have adequate reasons for delay, but if he has he owes it to the profession to explain those reasons As we have previously said, all the doubts and uncertainty that prevail are doing no good The profession is anxious to supply the country with the best medical service in the world, and it will do so if it be consulted and properly treated Will not the War Minister give us that opportunity?

HOSPITAL SUNDAY AND THE NATIONAL ANTI-VIVISECTION SOCIETY.

LAST Sunday, June 16th, was Hospital Sunday, the one day in the year when nearly all Christians and non Christians lay aside their differences and unite in trying to do their utmost to help the sick, the poor, and the needy We say "nearly all" because the National Anti Vivisection Society and its energetic honorary secretary, Mr Stephen Coleridge, introduced a false note into the harmony by causing to be distributed at church doors a leaflet quoting a letter which had "been sent to the incumbent of this church" asking the said incumbent to use his influence to insure the payment of the subscriptions of his congregation to those hospitals only "that make no such diversions from their general funds" The "such diversions" were sums granted to the support of medical schools "which are places wherein animals are vivisected' We are glad to see that the incumbent did not reply to Mr. Coleridge, and therefore that "the National Anti vivisection Society desires to place the letter before you and to inform you that should you wish to have full information on this matter before giving your money to the Mansion House Fund, such information will be found in the 'Guide to the Charitable' issued by the society which will be supplied to you gratis on application at the society's office, 92, Victoria street, Westminster" We applied for the "Guide to the Charitable," the proper title of which is "A Guide for the Charitable in the Disposition of their Gifts and Bequests, but we were charged 3*d* However, let that pass, we simply say that Mr Coleridge's action "is not cricket,' it is not the way to play the game We are not alone in this opinion, as is exemplified by Canon Fleming's letter in the *Times* of June 17th Mr Coleridge deliberately charges the Hospital Sunday Fund and the authorities of hospitals with malversation The medical education given in a medical school is as much for the benefit of the patients as are bandages, beds, or drugs, and the hospital authorities have a perfect right to subsidise their schools if they like We cannot check the accuracy of all Mr Coleridge's statements, but we notice that in the account of Charing Cross Hospital it is stated in red ink that "Drs Phillips and Arkle, though not otherwise connected with the hospital or the school, are licensed to perform experiments at the medical school Dr Phillips may be, but Dr C Arkle has been dead since 1899 Nothing that Mr Coleridge or any one else can say will alter our opinion of his action, so he may spare himself the trouble of writing two column letters to us There is apparently one incumbent who has taken up the attitude of running with the hare and hunting with the hounds, for according to a contemporary Archdeacon Wilberforce, unwilling completely to boycott the Hospital Sunday Fund on account of "vivisection," intended to have two collections, the proceeds of one of them to be devoted to some hospital or hospitals defined as "non vivisectionist" Whether the venerable gentleman mentioned actually conceived or carried out any such plan we do not know, but it is to be hoped that he or any other clergyman who addressed a congregation on the question of experiments on animals and its bearing upon subscriptions to hospitals was discerning or candid enough to point out in doing so that the conscientious "anti vivisectionist" who does not subscribe to the Hospital Sunday Fund on account of experiments made in individual hospitals must equally refuse to contribute to any hospital in which any operation is ever performed or any drug administered the effect of which was originally tested in any hospital or laboratory by experiment upon any living thing, except only upon a human being, and we need hardly add that in order to be thoroughly consistent the "anti vivisectionist" must also decline to avail himself of surgical or medical science in most of the ills that may happen to him, or he will himself be profiting by "vivisection"

As, however, every progressive step in medicine or surgery must in the nature of things be an experiment, the "anti-vivisectionist" at the present moment has three courses open to him. He may proclaim himself an enemy to all progress in medicine and surgery and subscribe to nothing; or he may endeavour to discover a hospital in which all the work done is based upon experiments made not upon animals but upon patients, although where he will find this institution we cannot pretend to say; or, thirdly, he can still reconsider his position and send a belated but acceptable contribution to the Hospital Sunday Fund.

FOOD STANDARDS.

A MOST important announcement has been made in Parliament to the effect that it is proposed to fix a standard for milk under which, for the purposes of the Sale of Food and Drugs Acts, a presumption would be raised that milk was not genuine unless it contained 3 per cent. of milk-fat and 8·5 per cent. of non-fatty milk solids. Regulations to this effect are being prepared, and it is suggested that these regulations should come into force on August 1st. The principle of standards for food becomes thus officially recognised, and this experiment in legislation will be watched with interest while doubtless in some quarters it will be viewed with dismay. The question of adopting standards in the matter of milk has been discussed for a great many years, and many persons have doubted the feasibility of insisting upon any limits, but public analysts have long recognised the necessity of having a legal limitation, if the evidence of analysis is not to be brought into discredit and if the adulteration of milk with water in particular is to be suppressed. For years past the Society of Public Analysts have adopted as minimal limits for fats 3 per cent. by weight, and for solids not fat 8·5 per cent. by weight, and these limits have been accepted as satisfactory by most analytical chemists not only in this but in other countries. It is well known, of course, that milk occasionally falls below this standard, although there may be no doubt about its derivation straight from the cow. But such cases are exceptional and should be regarded as abnormal. In the experience of those who deal every day with the composition of a variety of milks the limit of 3 per cent of fat is quite reasonable for the mixed milk of the whole herd. Genuine milk rarely, if ever, falls below this limit. Moreover, this limit allows, we think, for all seasonal variations. The question remains whether particularly rich milk will, in view of a legal requirement, be diluted down to the standard. This possibility is perhaps the only serious argument against the principle of standardisation. We have suggested more than once that the buyer of milk should obtain a guarantee from the seller of the quality of the milk supplied and no reasonable person would object to pay a price in accordance with this quality. We certainly do not think that the legalisation of a standard will be a hardship to the milk dealer. The attenuation of milk by the abstraction of cream or by the addition of water is a much too favourite practice and it must be stopped. The adoption of a standard will, we believe, have the effect of improving the quality of the milk supplied, and the Society of Public Analysts may be congratulated upon the fact that the Government have adopted exactly the limits and standards of milk which the society decided upon for the guidance of their members in active practice some years ago. Other questions are also pressing in regard to the laying down of standards for foods, and a committee is shortly to be nominated by the President of the Board of Agriculture who will be asked to consider a large amount of evidence on the proposal to adopt a butter standard. The administration of the Food and Drugs Act has been a much-debated subject by parliamentary committees during the past few years, but nothing so definite as the proposal of food standards—though, as we have urged all along, such standards were required to clear away many difficulties—has ever been decided upon. No subject has ever given rise to more contention than that of fixing standards for food, but it would seem that at last this country is to adopt a method of administration on the same lines as have been adopted by other countries years ago, lines which experience teaches to have been expedient and productive of public good.

THE COMPLIMENTARY DINNER TO SURGEON-GENERAL JAMESON, C.B.

THE complimentary dinner to be given to Surgeon-General Jameson, C.B., will take place on Wednesday, July 24th, at the Hotel Cecil. The cost of the tickets will be 25*s.* All members of the medical profession, whether in His Majesty's services or not, are invited to attend. Gentlemen who wish to be present are requested to send their names to one of the honorary secretaries, Mr. G. Lenthal Cheatle, C.B., F.R.C.S. Eng., 117, Harley-street, W., or to Mr. Cuthbert S. Wallace, F.R.C.S. Eng., 75, Lambeth Palace road, S.E., who will communicate with them with regard to details.

PLAGUE IN CAPE COLONY.

A TELEGRAM received at the Colonial Office on June 13th, gives the following statistics of plague at Cape Town for the week ending June 8th. Fresh cases: Europeans, 7; coloured persons, 2; Malays, 4; Indians, Chinese, Natives, 0; total, 13. Corpses found: Europeans, 0; coloured persons, 2; Indian, 1; Malays, Chinese, Natives, 0; total, 3. Deaths (including corpses found), Europeans, 1; coloured persons, 5; Malay, 1; Indian, 1; Chinese, Natives, 0; total, 8. The total cases up to June 8th are as follows: Europeans, 180; coloured persons, 313; Malays, 53; Indians, 11; Chinese, 1; Natives, 142; total, 700. The total deaths have been—Europeans, 58; coloured persons, 164; Malays, 36; Indians, 9; Chinese, 0; Natives, 59; total, 326. One case has occurred under naval and military control. The area of infection remains unchanged.

THE RATING OF WATER RESERVOIRS.

THE rating of water reservoirs is likely to engage some attention in the near future. In the neighbourhood of Hampton and Sunbury, in addition to the immense reservoirs already existing, it is in contemplation to cover something like 6000 square acres, or about 10 square miles, for additional storage. Recently the Hampton-on-Thames Urban District Council rated some of these massively-constructed water stores on the same basis as any other building used for the storage of goods. This the water companies resisted and a test case was submitted to the House of Lords. It was held that a reservoir was chargeable only as land covered by water, and under Section 211 of the Public Health Act, 1875, was rateable at one-fourth only of the full rateable value. The inhabitants of Hampton and Sunbury, who have recently been spending large sums upon sewerage systems and disposal works, feel greatly aggrieved at this wholesale diminution of their prospective income. At a public meeting held at Sunbury on June 3rd heroic measures were resolved upon. The existing law was pronounced to be iniquitous and unjust; it was determined that it must be altered and steps were resolved upon towards forming a combination with other urban district councils to achieve the reform. Although they have a distinct case, the inhabitants of Hampton and Sunbury will be well advised not to go too quickly. Superficially it seems an anomaly that one structure costing many thousands of pounds, used for the s
of a marketable commodity sold at a profit, should be

at a lower standard than another simply on account of its contents. It is also hard that a rural suburb, renowned for its sylvan beauties, should be denuded of its trees and generally rendered more or less hideous, while the wealthier resident population is driven away, to the general detriment of the remainder, and this without any compensatory advantage. But, on the other hand, very many years would elapse before 6000 square acres in the district would be covered with ordinary buildings, paying the full rating. The urban district council would in the meanwhile have to spend large sums upon miles of sewers and paving, would have to maintain roads—which means lighting and watering—and would also have to pay for police work, while an increase of the indigent population would be certain. These expenses in the case of the reservoirs are almost nominal, whilst the water companies are even now voluntarily paying the full rating on the poor-rate. The people of Hampton and Sunbury will be prudent to consider further before engaging in a Quixotic attempt to reform the existing law. It is very doubtful if much support will be extended to them from other district councils, very few indeed of which are in a parallel position.

INTERMITTENT CLAUDICATION OR LIMPING: ITS PATHOLOGY AND TREATMENT.

PROFESSOR DAVID RIESMAN of the University of Pennsylvania deals, in *American Medicine* of May 25th, with the interesting and somewhat rare condition known as "intermittent claudication"—a phenomenon first described by Charcot in 1858. The expression was then borrowed from veterinary medicine, in which it was employed to designate an intermittent painful limping or paralysis occurring in horses. Recently attention has been drawn to this condition in man by the studies of Erb and Goldflam. The cardinal symptoms in the human subject are as follows. The patient starts out to walk and does so for a short distance with perfect or almost perfect ease. Then he begins to experience pain and numbness, and often a distressing cramp in one or both legs, usually in the calves or feet. Further walking becomes difficult or impossible and he is compelled to rest. After a few minutes, however, locomotion can be resumed, only to be again interrupted by a return of the pain and cramps in the legs. The patient thus has intermittent attacks of limping. Physical examination of the legs shows a very characteristic symptom—viz., an absence of pulsation in the arteries of the feet, chiefly the dorsalis pedis and often the posterior tibial artery. Professor Riesman states that pulsation of the dorsalis pedis artery is never absent in health, and Erb noted its presence in 99 per cent. of general hospital patients, its absence in 1 per cent. being due to œdema of the legs, elephantiasis, or arterio-sclerosis, all of which acted as obstructions to the circulation in the affected limb. Sensation in the limbs was normal in patients who had intermittent claudication, but paræsthesia (numbness, formication), pain, and coldness might be present, while pallor and dryness of the skin of the legs were common. That it was important to recognise the disease was shown by the fact that gangrene occurred seven times in 24 cases collected by Goldflam. The majority of patients are of the male sex—11 out of 12 observed by Erb and all the 24 cases of Goldflam—the ages varying from 32 to 60 years Pathologically the most important lesion is an obliterating endarteritis in the lower limbs, similar to that found by Mitchell and Spiller in the arteries of the toe in erythromelalgia. Among the etiological factors were syphilis, alcohol, exposure, tobacco, and perhaps diabetes. As, however, arterio-sclerosis is common and intermittent claudication is rare it is necessary to assume that other factors contributed to bring about the latter affection. Charcot inclined to the belief that the muscles lost their irritability and possibly suffered a change analogous to cadaveric rigidity, as in the well-known experiment of Stannius of ligature of the abdominal aorta in animals. It is interesting to note that the majority of the patients whose histories are recorded were excessive users of tobacco and were of the Hebrew race. The following case is illustrative. A man, aged 39 years, a travelling salesman, had smoked and chewed tobacco to excess all his life. He then became ill with muscular rheumatism (?) and had to take to his bed. He lost flesh considerably after this. One day, while walking, he experienced severe and sudden pain in the sole of the left foot and had to take a cab to reach his home. After this he developed all the symptoms of intermittent claudication. In June, 1900, he had an obscure "attack" with loss of speech and of power in the right arm, but apparently recovered after two weeks' treatment with iodides. Pulsation was now noticed to be absent from the dorsal artery of the left foot and to be slight in the right. Some improvement resulted from treatment with hydrargyrum and iodides, but only temporarily. Professor Riesman says that diet should be largely vegetable and that red meats, alcohol, tea, coffee, and tobacco should be forbidden during treatment. Alkaline waters are helpful. Fatigue should be carefully avoided. Massage did not prove helpful in the present case.

SELF-DRUGGING.

THE pernicious habit of self drugging has grown to be a source of untold mischief. It is greatly assisted by the enormous improvements which have been brought about in recent years in pharmaceutical preparations. 30 or 40 years ago medicines were bulky and had to be taken in large doses of generally a nauseating flavour. But now, owing to the invention of the various "-oids," "-forms," "-ettes," and "-ines," medicines can be taken in small doses and with a minimum of trouble. The columns of the daily press are given up to flaming advertisements setting forth in more or less scientific language the various feelings of *malaise* engendered by hepatic insufficiency and constipation, and the sufferer is assured that if he will take some or other preparation "that tired feeling" or any other of the thousand-and-one symptoms attributable to dyspepsia or lithæmia will vanish like a dream when one awaketh. The advertisements to which we take exception are not quack medicines. They undoubtedly are useful in the condition described under certain circumstances But the dangerous thing about them is that they induce the public to drug themselves and very possibly to omit to seek treatment for what may not be simply constipation, gout, or dyspepsia, but possibly the outcome of malignant disease. This is why we think that such advertisements are in no way right. They are, if not intentionally deceptive, at all events practically so.

THE NEW RADCLIFFE LIBRARY AT OXFORD.

JOHN RADCLIFFE, M.D., by his will dated Sept. 13th, 1714, bequeathed most of his property to the University of Oxford, and one of the results of this will was the Radcliffe Library which was completed in 1747. In a Convocation held at Oxford on Tuesday last the degree of D.C.L. *honoris causâ* was conferred upon Cornelius C. Dalton, C B, Master of the Drapers' Company, on the occasion of the formal handing over to the University of the new Radcliffe Library built by the Company at a cost of over £21,000. The building adjoins the museum and has been erected in the Renaissance style from the design of Mr. T. G. Jackson who has already done such good work for Oxford. The Drapers' Company being in the possession of funds now no longer applicable to their original purpose, it occurred to them whilst Dr. Henry Bond, the principal of Hertford College, was serving his term of office as Master of the Drapers' Company, that some of these funds might be devoted to the teaching of science in the University of Oxford. Dr. Bond approached the University on the matter and the new library was the outcome. This was the little history of the movement which Dr. Dalton gave on handing over the buildings to the University. We are happy to be able to add our meed of congratulation to the Drapers' Company for their munificent action. The great City companies have often been threatened with spoliation by those whose desire seems always to be to take away from him that hath, but so long as corporate bodies distribute their wealth after the manner of the Drapers' Company there is but little fear that they will be robbed.

THE MEDICAL ACTS AMENDMENT BILL.

The Medical Acts Amendment Bill was introduced in the House of Commons by Sir Richard Jebb, M.P. for Cambridge University, on Monday last. This Bill gives the General Medical Council power to erase from the Medical Register for a limited period the name of a registered practitioner who has been adjudged guilty of misconduct in a professional respect. The General Medical Council would thus be able to deal fitly with cases which can be met by temporary suspension from practice. A second object of the Bill is to enable medical authorities to deprive a practitioner whose name has been erased from the Medical Register of the degrees or diplomas obtained from that authority. At present the bodies which grant registrable qualifications do not all possess the same powers of taking them away from unworthy persons. The Bill also provides that penalties recoverable under the Medical Acts shall be paid to the General Medical Council. The measure is well backed and should become law.

"THE EXTERMINATING COLLECTOR."

In an annotation published under the above heading, which appeared in The Lancet of June 8th, p. 1613, we commented upon sundry statements made in letters to the *Times* written by Professor L. C. Miall and Professor R. Meldola concerning a programme of field studies in natural history which was issued apparently by the Essex Technical Instruction Committee, Biology Section. We say "apparently" because Professor Meldola said that the programme was unofficial. Mr. David Houston, F.L.S., has now sent us a copy of the programme in question which is, however, headed "County of Essex Technical Instruction Committee," by which we see that with regard to the vacation course in the New Forest, "members of the party will of course refrain from up-rooting rare or scarce specimens." The paragraph about collecting duplicates which appears on p. 7 of the programme does not refer to the New Forest but to "the Saturday or other rambles" in Essex. We may therefore possibly have been wrong in assuming the Essex Technical Instruction Committee to be wishful to collect rare plants in the New Forest, but why does Mr. Houston on p. 9 point out that four plants specially named as "rare" should be "particularly sought after"? All the same we most earnestly hope that most stringent measures will be taken to preserve not only our rare flowers and plants but also our rare animals. Only recently we have seen reported in the daily press the destruction of the badger and the otter, both wild animals, of which there are far too few. Granted that the otter destroys fish and the badger eats rabbits there is no reason why the angler should have his sport protected at the expense of such an interesting animal as the otter, and as for rabbits they are so prolific that the few eaten by a badger can make little or no difference. If the destruction of pheasants or partridges can be laid at the badger's door we suppose that he will have to go, but we fancy that the hedgehog is a greater criminal in this respect, at any rate, as regards eggs. Wild life in England is in a parlous condition and those animals which remain should, in our opinion, be protected as far as possible.

EPSOM COLLEGE.

The preliminary list of stewards of the festival dinner of the Royal Medical Benevolent College, Epsom, to be held at the Hotel Cecil, on Tuesday, July 9th, in aid of the fund for the pensioners and foundation scholars of the college, will be found in our advertising columns and promises well for the success of the object in view. We have often commended this excellent institution to the consideration of the medical profession and take this opportunity of doing so again. Epsom College ought to be supported by every medical man in the country, for the work that it does is of immense value. The pensions that it distributes represent to some of our old and unfortunate brethren the difference between life and death, while the service that it renders to the orphan children of medical men can with difficulty be calculated. Would that Epsom College could grant more pensions and receive within its walls more foundation scholars. At the present moment, however, the institution finds it almost impossible to respond to the calls made upon it, and we would urge upon our readers that they should make an attempt to support it by donations and regular subscriptions.

NATURE AND TREATMENT OF DIPSOMANIA.

Dr. P. C. Remondino of Los Angeles, California, in a paper on dipsomania contributed to the April number of the *Quarterly Journal of Inebriety*, draws attention to the singular features in the history of the dipsomaniac—viz., the recklessness manifested in the period of drinking while it lasts and the practice, for the most part, of total abstinence during the interval. He also makes certain practical suggestions regarding the climatic treatment of these cases, drawn from a specially large experience in them. Members of the dipsomaniacal class are to be found in all ranks of society, and it has long been a mystery to their friends how men of intellectual culture and even of refinement can continue to repeat such orgies of drink and dissipation, of the consequences of which they are fully conscious in the intervals. One of the cases recorded was that of a medical man, a person of "high intellectual culture and morals" and always in the enjoyment of excellent health. His periodic attacks would begin in most unusual fashion. For days before an attack he would cautiously gather bottles of brandy, gin, whisky, or other liquor, and secrete them in places likely to escape detection—e.g., in his hunting-boots, behind books in bookcases, and in other corners. When all was ready his spell of debauchery would be inaugurated at nightfall. Being missed at meals by his friends, who always feared the cause of his disappearance, he would be found in his room in a "glorious state of intoxication." He would walk up and down in a rigidly erect attitude, hardly able to articulate, and his eyes would have a wild, fixed, and unnatural stare. As many bottles as could be found would be removed, but the patient would still manage to get a few from their hiding-places and so finish his drinking spell—an ending that always came when his stomach refused to hold liquor any longer. A week of retching and vomiting, with headache, would follow, and he would suffer from attacks of deep contrition and slight suicidal promptings. He would then leave home for a fortnight's rest and convalescence, and return to his work in good condition. In a second case the patient's attacks followed overwork and cerebral fatigue.

He would then take a tonic (tincture of cinchona or other alcoholic drug) and repeat the dose a few times "to steady himself" as he said. The craving for drink would now come upon him with great intensity and he would drink until he passed *into a helpless stupor and his stomach refused* any more. Then followed days of intense neuralgia, gastralgia, "heavings," and repentance. When quite sobered he would read and study books on temperance, and, perhaps, deliver a lecture on the benefits of total abstinence before some local temperance association and rejoin some lodge which would receive him as a brand saved from the burning. After this he would remain an exemplary teetotaler until some new accident hurled him from grace. The periods of strict temperance in this patient lasted from a few months to two years. In two other cases, both laymen of more than average intelligence, attacks of dipsomania would be brought on "through the influence of a peculiar hysterical condition of the whole nervous system," precipitated by any excitement in social or municipal matters in which they took part. An unfortunate *condition of unstable equilibrium and weakness of the nervous* system would result, which imperatively called for some stimulant in these two persons. Dr. Remondino points out that in cases of dipsomania a neurotic heredity was often present. In the case of one patient with a gouty taint and of another with chronic malaria, cures of the dipsomania were effected by treatment of these bodily disorders, and in the latter case removal to a more congenial climate made the cure permanent. A humid and temperate climate with a "sedative" atmosphere was better than a hot and dry one for dipsomaniacs. Occasional cures might be effected by auto suggestion or by hypnotic treatment.

PAPER AS A WRAPPER.

NOT the smallest use amongst the great variety of uses to which paper is put is that of a wrapper and it would be hard to find a substitute. There is, of course, a special paper made for wrapping articles of food—as, for instance, butter, biscuits, and tea—but very frequently, and especially amongst the poor, almost any paper material is employed for the purpose. Thus a pennyworth of pease-pudding is commonly supplied in a piece of any old waste newspaper, or in the same way a slice of boiling hot ham, a bloater, or a well-oiled slice of fried fish. Some commodities, indeed, are supplied even in a well-nigh liquid state in this way. A boy in the street may frequently be seen licking his pennyworth of tamarind preserve from a piece of newspaper. The spectacle is not very edifying, and when we think of the possibility of the paper and the heavily-inked print upon it containing injurious substances we may shudder. Of course, the ubiquitous organism is bound to be present and not unlikely it may be a pathogenic one considering the dirty environment under which waste newspaper is frequently to be seen. In these days, too, when science would seem to show that arsenic in varying quantities is as ubiquitous as the microbe, the newspaper may become a dangerous wrapper. Such things as salt meats or salt fish would be calculated to exert a solvent action upon any irritant present. The print may often be found reproduced on the fat of a slice of salt beef or on the daub of pease-pudding. This aspect of the purity of newspapers is, therefore, worth considering and we are glad to be able to record, as the result of a recent inquiry in the laboratory, that at any rate the London newspapers are as a rule free from any reproachable substance. This is all the more satisfactory when we consider the cheapness nowadays with which newspaper production is required to be done. We have examined the penny newspapers and the halfpenny newspapers, the white newspapers and the *coloured newspapers, but in no case could* we find even traces of substances that are regarded as injurious. And this result exonerates also the printing ink, although we found when operating upon printing ink in bulk just the bare indication of arsenic, but the quantity of printing ink operated upon would represent a whole file of papers. Possibly a trace of arsenic occurs in the Prussian blue used in printing ink. Even the coloured evening newspapers are free from objection, although an aniline dye is calculated to excite suspicion. However, the green *Westminster Gazette*, the pink *Evening News*, *Star*, *Globe*, and *Sun*, were alike found to contain innocent colourings in infinitesimal quantity, while no irritants could be found on analysis. Of course the manufacture of paper involves the use of chemicals, notably lime, soda ash, chlorine, sulphuric acid, chromium salts, hydrochloric acid, and alum, and it is conceivable that in careless or cheap manufacture these substances or their impurities, amongst which may be reckoned arsenic, might be retained in the paper. In the light of our examination, however, the London newspapers at any rate may be *said to be satisfactory on these heads, and therefore any* objection against the use of the newspaper as a food-wrapper, apart from bacteriological possibilities, can only be sentimental.

THE BONES OF ST. THOMAS OF CANTERBURY.

"WHERE are now the bones of the famous and wise goldsmith, Weland? I call him wise, for the man of skill can never lose his cunning and can no more be deprived of it than the sun may be moved from his station. Where are now Weland's bones or who knoweth now where they are?" So wrote our great King Alfred more than 1000 years ago in his translation of the "De Consolatione" of Boethius in one of the reflective passages with which he interlarded the original text. The words came forcibly to our minds on seeing the little pamphlet by Mr. Pugin Thornton *entitled, "Becket's Bones."*[1] The pamphlet *arose from the* discovery of some bones in the crypt of Canterbury Cathedral during some excavations made in 1888. They were lying in a coffin within a few feet of the tomb in the crypt where the great archbishop was buried in 1170. From this tomb his bones were removed to the shrine in Trinity Chapel, where they rested undisturbed until the advent of Henry VIII. Mr. Pugin Thornton discusses the question as to whether or not the bones found are the bones of one who in his time was the most popular English saint. He comes to the conclusion that they probably are *and gives eight reasons for so doing. Among these are the* following. Apart from the evidence of injury to the skull the bones evidently belonged to a tall man, and Becket was over six feet in height. They had evidently been reburied in the place where they were found, for they were arranged in a certain order, the long bones crossing one another. We should say that the late Father Morris who was at first in favour of the bones being those of the saint afterwards argued strongly against this view. After Mr. Thornton's examination the bones were re-interred where they were found, but no inscription marks the site. We think that a hypothetical inscription might well be added, for except the building itself we fancy that there is no memorial of the Archbishop in the cathedral, and whether we look upon him merely as an Archbishop or as St. Thomas of Canterbury there is no doubt that he was a very great man. Apart from his influence in life he exercised for centuries after his death an influence over the thoughts, the minds, and the literature of Englishmen to which it is hard to find a parallel. Perhaps his memory is best preserved by the "Canterbury Tales" and by the solemn yew trees which mark the Pilgrim's Way from Southampton to Canterbury through Surrey and Kent. But, as Sir Thomas Browne says, "Who knows the fate of his bones or how often he is to be buried? Who hath the oracle of his ashes or whither they are to be scattered?"

---

PRACTICAL MICROSCOPY.

As the medical profession is interested in the study of microscopy our readers may like to know that a new series of articles dealing with the practical side of microscopy, together with notes and queries, correspondence, and descriptions of new apparatus, are appearing each month in *Knowledge* under the editorship of Mr. M. I. Cross. The articles give good and practical information on the subject, and being edited by one of the joint authors of the well-known handbook, "Modern Microscopy," are sure to prove valuable.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.

THE provincial meeting of this society will be held on Saturday, June 29th, at the Medical Institution, Hope-street, Liverpool. From 3.30 P.M. to 5 P.M. there will be an informal exhibition of cases by Mr. Robert Jones, Dr. James Barr, Dr. C. J. Macalister, Mr. G. P. Newbolt, Mr. K. W. Monsarrat, and others, and at 5 P.M. the following papers will be read: Some Remarks on the Etiology of Rickets, by Dr. Henry Ashby; Tubercle of the Choroid, by Dr. George Carpenter and Mr. Sydney Stephenson: Note on a Case of Syphilis Transmitted to the Third Generation, by Dr. D. M. Hutton; A Short Note on the Surgical Treatment of Meningitis in Children, by Mr. K. W. Monsarrat; Observations on Cirrhosis of the Liver and Endocarditis in Children, by Dr. C. J. Macalister; A Note on the Treatment of Endocarditis in Acute Rheumatism and Chorea, by Dr. Richard Caton (introduced); Removal of a Foreign Body from the Second Part of the Duodenum, by Mr. R. Clement Lucas; A Case of Pneumococcal Peritonitis, by Dr. John H. Bryant; and Bimanual Examination in Diagnosis of Abdominal Disease in Children, by Dr. James Carmichael.

THE NATURE AND TREATMENT OF TICS AND ALLIED DISORDERS.

IN the *Revue Neurologique* of April 30th Dr. H. Meige and Dr. E. Feindel publish an interesting and practical paper on the subject of tics and allied disorders of movement of nervous origin and deal briefly with the treatment of some varieties. The cases studied were 20 in number and had been under observation for some years. They agree with Charcot[1] that tics are automatic and irrepressible movements which are caricatures of natural movements. The present study is especially concerned with tics of the face and neck which may be accompanied sometimes by movements of the shoulders and respiratory sounds. Among the causes imitation of gestures holds a prominent place, especially in the case of young "tiquers." Tics may be thus learnt and by repetition they may become habitual. A case is given of a child with oculo-motor tics which were acquired by imitation of the mother. The mother was cured of the habit and the child ceased to exhibit the tics thereafter. Echolalia, coprolalia, and the utterance of bizarre and uncouth sounds (grunts and the like) are other instances. Twitching of the eyelids as if from irritation by a foreign body, and blinking as if in the presence of excessive light are common tics. The latter is sometimes due to feebleness of will and sometimes to contracture and may be corrected by "gymnastics" of the eyelids. Tics of the lips and tongue are frequent, singly or combined, as poutings, suctions, biting of the lips, and movements of the jaws. Some are accompanied by tics of smelling, respiration, and phonation. Squirming of the head and neck as if irritated by a tight collar is included by Brissaud under the title "mental torticollis." Treatment should be directed towards the discovery and removal of those whom the patient imitates and the elimination of any local irritation. Regulated exercise of the muscles affected may complete the cure.

ACCIDENT TO PROFESSOR VIRCHOW.

WE learn with regret that Professor Virchow has met with an accident. While out walking he was blown by a very high wind against a tree and sustained an injury to the head. Happily, assistance was quickly obtained and the professor, who was unable to walk farther, was taken home in a carriage and the necessary surgical aid was rendered by his medical attendant. There is said to be no reason for any immediate anxiety, but it must not be forgotten that Professor Virchow is approaching his eightieth anniversary; moreover, he has been in indifferent health for some time past.

LIVERPOOL SCHOOL OF TROPICAL MEDICINE: DEPARTURE OF THE FIFTH ANTI-MALARIA EXPEDITION TO WEST AFRICA.

Major Ronald Ross, F.R.S., late I.M.S., accompanied by Dr. Logan Taylor, recently assistant lecturer in pathology at the University of Glasgow, sailed from Liverpool on June 15th, by the steamship *Axim*, for the West Coast of Africa under the auspices of the Liverpool School of Tropical Medicine, with the object of attempting to exterminate the mosquito which is supposed to be the transmitter of malarial disease. This is the fifth expedition organised by Major Ross and the first occasion upon which Dr. Taylor has associated himself with the work. Major Ross proposes to stay in West Africa about six months, but the length of his sojourn will depend upon the progress made. It is quite probable that the Colonial Office, which is impressed with the importance of the investigations, may shortly send a representative to assist in the work. Mr. Chamberlain has shown his sympathy with the expedition by sending a message wishing it every success, and has also intimated that he has instructed the Governor of Sierra Leone and other Government officials to give to Major Ross and Dr. Taylor all the assistance in their power. A large contingent, representing the Liverpool School of Tropical Medicine, assembled at the landing-stage to give Major Ross and Dr. Taylor a hearty send-off, amongst whom were Mr. Alfred L. Jones (the chairman), Lady Ross (the mother of Major Ross), Mr. W. J. Davey (of the firm of Elder, Dempster, and Co.), Mr. William Adamson (the vice-chairman of the school), Professor Rubert Boyce, Dr. H. E. Annett (a member of previous expeditions), Mr. F. C. Danson (a former President of the Liverpool Chamber of Commerce), Mr. A. H. Milne (secretary of the school), Mr. T. H. Barlow (secretary of the Liverpool Chamber of Commerce), Mr. John Holt (vice-chairman of the West African Association), and many others. Mr. A. L. Jones said he was glad to say a few words of congratulation and appreciation of the objects of the expedition on behalf of the Liverpool ship-owners and merchants. The Liverpool School of Tropical Medicine had done good work in many ways, and whether the mosquito theory be accepted or not no one could deny the accuracy of science. From the fact that the theory was supported by Lord Lister and other eminent scientific authorities there was little doubt as to its ultimate success in protecting people from the difficulties and dangers of tropical climates. In thanking Major Ross and Dr. Taylor, on behalf of Liverpool and the country, Mr. Jones hoped that they would be successful in their researches. Mr. Jones also assured Major Ross and his colleague that if anything was required in the way of funds Liverpool people would gladly provide it. Mr. Jones contended that if the West Coast of Africa was made as healthy as India it would be due to the energy of men like Major Ross, who laboured against the numerous difficulties encountered in tropical countries in the interests of science, trade, and humanity. As the tender left the *Axim* hearty cheers were given by the distinguished assemblage for Major Ross and Dr. Taylor.

THE LATE MR. THOMAS BOND.

A POST MORTEM examination upon the body of the late Mr. Thomas Bond, whose death we recently chronicled, throws a light upon a tragedy that has much affected the medical profession. Microscopical examination of the prostate gland showed it to be not only enlarged but affected with scirrhus This explains the agonising pain which the unfortunate patient experienced during the last three or four months of his life, pain which, in the end, upset the mental balance and terminated the valuable life of a highly respected *confrère*.

DEATH REGISTRATION IN SCOTLAND.

THE *Glasgow Herald* of June 8th contained an interesting letter from Dr T. Colvin calling attention to the dangers arising out of the system of death registration in use in Scotland, which he stigmatises as chaotic. The reforms which he suggests will to some extent explain the present condition of things. He urges (1) that registrars should be empowered to refuse a burial order until the applicant produces a medical certificate of death signed by a duly qualified medical practitioner; and (2) that in all cases of sudden death where the deceased has not been examined by a medical man for a considerable time prior to his death there should be a coroner's inquest to detect and to prevent criminal practices of all kinds In the case which prompted Dr Colvin's letter a working man went to a registrar and told him that his child, having been attended for three days by Dr. Colvin for congestion of the lungs, was dead. A burial order was thereupon given to him by the registrar, but upon the registrar sending a medical certificate to Dr Colvin with a request that he should sign it the following state of affairs came to light Dr. Colvin had not attended the child, the child was not dead, and the fraud, for which the father was sentenced to 30 days' imprisonment, had apparently been perpetrated in order to obtain some privilege accorded by employers to bereaved parents We can only say that a system under which such an incident as that related is possible, and may, as far as Dr. Colvin informs us, take place at any time, is one which urgently needs reform. The English system is far from perfect, and a new system inaugurated in Scotland and avoiding the defects of that prevailing in this country might prove to be an experiment which would be very useful to both countries.

MEDICAL EXCURSION TO FRENCH MINERAL WATER RESORTS.

THE details of this year's trip to the mineral water stations of France have now been arranged as follows. The rendezvous will be at Uriage, near Grenoble, at which place visitors must arrive on Saturday, August 31st, or at latest on the morning of the following day. The trip will occupy exactly 12 days and will terminate at Thonon, on the Lake of Geneva In the interval the following places will be inspected, some of which, it will be observed, possess an interest which is general rather than scientific: Grande Chartreuse (Sept. 2nd); La Motte (Sept. 3rd); Allevard and Salins Moutiers (Sept. 4th); Pralognan (Sept. 5th); and Brides-les-Bains and Challes (Sept. 6th). On Sept. 7th Aix-les-Bains will be reached, and the day is to be spent in inspecting the city and its environs, Marlioz, Lake Bourget, and Hautecombe The following day will be occupied with an excursion to other places in the neighbourhood On Monday, Sept. 9th, the excursion will be continued as follows: Hauteville Sanatorium (Sept. 9th); Divonne (Sept. 10th); St Gervais (Sept 11th); Evian and Thonon (Sept. 12th). The price to be paid is 300 francs (£12 10*s*), and this will include everything from the point of rendezvous to the moment of breaking up Moreover, a railway ticket at half price can be obtained from any place in France (say Calais or Dieppe) to Uriage, and a similar ticket from Thonon back again. As in former years the tour will be under the direction of Professor Landouzy who will at each place give a short lecture on the composition of the waters, the balneological methods employed, and their therapeutic indications. Anyone intending to take part in the tour should communicate with Dr. Carron de la Carrière, 2, Rue Lincoln, Paris, stating (1) his name and address, legibly written; (2) the point at which he will enter France; and (3) the day on which he will arrive at Uriage. A cheque for £12 10*s* may be inclosed, or it may be sent separately to M le Directeur du Crédit Lyonnais, Agence B. Compte, V E M, Place de la Bourse, Paris. These details must be attended to before August 15th, after which date no application will be considered. Intending participators are strongly advised to reduce their personal luggage for the tour to the barest necessaries. In no case will dress clothes be required. Any further information may be obtained from Dr. Leonard Williams, 8, York street, Portman-square, W.

ONE EYE AT A TIME.

THE *Optician*, a widely circulated and well conducted journal, contains a paragraph in the number for June 14th which is, in our opinion, misleading. The statement is that a man on his travels, wearing a patch on one eye, is asked the reason of this proceeding. His reply is that he considers it to be advantageous to rest one eye; that as we do not use the two hands simultaneously neither should we use the two eyes, so that whilst one is working the other may be allowed to rest. Unfortunately for this view the analogy between the arms and their movements and the motions of the eye is very imperfect The nervo-muscular apparatus of the eyes does not correspond with that of the two arms. The muscles of the arms can be taught to work together or in opposition to one another, but no amount of practice will enable a man to move simultaneously the two eyes in opposite directions, either horizontally or vertically. The construction of the nerve centres is such that the eyes must roll in the same direction By closing the lids of one eye positive harm may be done, for friction between the globe and the lid of the closed eye will only serve to impede its movements and interfere with the due coördination of the muscle This effect is not unfrequently seen when one eye has for any reason been kept closed by a bandage, double vision often lasting for some time. To close one eye for the purpose of resting it seems about as sensible as it would be to tie up one leg and hop with the other on alternate days, or to plug one ear or nostril and rely upon the other for audition or for smell.

A BUST of Armauer Hansen will be unveiled at the Lunggaards Hospital in Bergen on the forenoon of August 10th Professor Virchow is issuing invitations in the name of the committee to prominent medical men of different countries to take part in this ceremony in order that it may prove an occasion of international professional fellow-feeling. Dr. Sandberg of Bergen is receiving the names of those invited who intend to be present.

AT the request of His Majesty the King His Royal Highness the Duke of Cambridge has undertaken to fill the office of President of the British Congress on Tuberculosis and will open the Congress at St. James's Hall, Piccadilly, W., on Monday, July 22nd, at 3 P.M.

HER MAJESTY QUEEN ALEXANDRA, who as Princess of Wales was for 30 years patroness of the Hospital for Diseases of the Skin, Blackfriars, S.E., has graciously consented to continue her Royal Patronage.

THE Master and Wardens of the Society of Apothecaries have issued invitations for a conversazione to be held at Apothecaries' Hall, Blackfriars, on Wednesday next, June 26th, from 8 to 11 P.M.

THE Past and Present West London Hospital dinner will be held at the Empire Rooms of the Trocadéro Restaurant on Tuesday next, June 25th, at 7 30 P.M.

ARMY MEDICAL DEPARTMENT REPORT FOR 1899.

I.

IT is unavoidable, we presume, that a considerable interval should ensue between the occurrence of the facts and medical transactions to which these reports relate and their publication. The information has to be drawn up and collected from the various military stations and commands and the various statistical returns have also to be revised and corrected before they can be embodied and issued in the form of a report which, being an official publication, has to be accurate. But it cannot be doubted that in the times in which we are living this has the effect of robbing such reports of much of the interest which they would otherwise possess. To the ordinary reader the perusal of an official history of past events and the examination of statistical tables and their results are not at the best of times an exhilarating occupation and they are only too apt to be regarded as a somewhat stale and unprofitable one. The consequence is that reports on the compilation of which great pains and labour have been bestowed often receive but scant notice, especially in the columns of current journalism. In the case of the Army Medical Service, moreover, the report intended for the information of Parliament and the public is usually issued first and separately, to be speedily followed by the more enlarged and expanded report containing an appendix embodying the special and more professional contributions of medical officers. It is to the latter, perhaps, that the main interest of the volume attaches, at least as far as the medical profession is concerned.

The reader will naturally turn first of all to the subject of the war in South Africa. But as regards South Africa we are told that no annual returns of sick are, for the present, forthcoming, and complete statistics for comparative purposes cannot be prepared until after the military operations have been brought to a close. The prevailing diseases previously to the outbreak of hostilities were, however, enteric fever and other fevers, dysentery, digestive disorders, venereal affections, and rheumatism.

The first pages of the report for 1899 give an excellent summary statement of the health of the troops at home and abroad, from which we glean the following:—

The average strength of the European troops serving at home and abroad, exclusive of South Africa, in 1899 was 201,004 warrant officers, non-commissioned officers and men. The total number of admissions to hospital was 173 204, and the total deaths were 1594. The admissions represent a ratio of 861·7 per 1000 of strength as above; the deaths one of 10·82 per 1000, on a strength of 204,720, which includes detached men not shown in the returns received. The statistics of the troops serving in the United Kingdom show that the admission and mortality rates were both higher than in 1898, but lower than the average rates for the preceding 10 years. The admission rate for eruptive fevers was practically the same as in the previous year. One case of small-pox occurred. Influenza was again prevalent, but did not appear in an epidemic form. Enteric fever showed a decline in the admission rate as compared with the previous year and the average rate, but the mortality rate was somewhat higher in both comparisons. Dublin with eight cases was again the station most affected. Of the cases of heat-stroke and sunstroke, 29 occurred at Aldershot, and 23 at the Curragh while manœuvres were being held. Eight cases of lightning-stroke occurred in a regiment on the march from Limerick to Thurles to participate in the Irish manœuvres, and practically the whole battalion is stated to have suffered from the effects of lightning. At Gibraltar the admission and constantly-sick rates were lower, but the death-rate was somewhat higher than in 1898. The admission and mortality rates for enteric fever were less than in the previous year. In the Malta command, which includes Crete, the health of the troops compared favourably with the previous year. In Canada the health of the troops was good, there being a decrease both in the admission rate and in the ratio of constant inefficiency as compared with 1898. The mortality rate was, however, somewhat higher. In Bermuda it is noted that the decline of enteric fever commented upon in the previous year's report was again maintained throughout 1899. The admission rate for venereal diseases, which is always extremely low in this command, had still further decreased.

At Barbadoes the health of the troops was good, but the ratios of sickness were higher than in 1898, though below the average rates. There was an outbreak of beri-beri during the year, the origin of which could not be traced to any special cause, but it is stated that the disease is frequently introduced into the island from the shipping. At Jamaica it is noted that the health of the troops, although good, was not quite equal to that in the previous year in consequence of the prevalence of malarial fevers and venereal diseases. In Mauritius the health of the troops was above the average. Plague was prevalent throughout the island, and was particularly severe at Port Louis, but owing to the strict military measures adopted to prevent the disease from spreading the troops were particularly free from attack, only one case occurring. There was a marked decline in the prevalence of malarial fevers. In Ceylon there was a marked increase in the admissions for malarial fevers, but this is believed to be due more to the importation of troops who had been affected with malaria elsewhere than to local causes. In the Straits Settlements the health of the troops was most satisfactory, the marked decrease in the admission rate for venereal diseases being especially noticeable, which decrease is attributed in a great measure to the increased supervision exercised by the municipal authorities over the bazaars, brothels, &c. There was also a considerable decrease in the number of admissions for malarial fevers. In China the ratios of sickness were higher than in 1898, chiefly due to the increase of admissions for malarial fevers. This is stated to be attributable to some extent to the arrival of a regiment which suffered severely while in Crete during the previous summer. Plague was again epidemic among the civil population, but the troops enjoyed comparative immunity, only two admissions and one death occurring. There was a further decline in the admission rate for venereal diseases. A local ordinance having for its object the prevention of the propagation of venereal disease came into operation in November and is said to be working satisfactorily. In India there was a decline in the admission, death, invaliding, and constantly-sick rates. The chief causes of sickness were, as usual, malarial fevers and venereal diseases, which together caused 48·6 per cent. of the admissions for all causes. Malarial fevers, enteric fever, venereal diseases, and dysentery were all less prevalent than in 1898, and there was only one admission for cholera. Notwithstanding the appearance of plague in epidemic form in several localities among the natives only a few cases are recorded among the troops. In Egypt the general health of the troops was very good, the admission, mortality, and constantly-sick rates being considerably lower than in 1898, and also than the decennial average rates. Plague occurred at Alexandria during the year among the civil population, but owing to the strict precautionary measures adopted no case appeared among the troops. Khartoum was in 1899 used as a station for the first time by British troops.

REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR 1899-1900.

II.[1]

Mr. W. H. Power attaches considerable importance to the auxiliary scientific investigations which were carried out during the year by the assistant medical officers of the Local Government Board. The first of these to which he calls attention (Appendix B, No. 1) was an experimental inquiry into the condition which has received the name of "pseudo-tuberculosis," a word which, as Mr. Power points out, was formerly loosely used to include a number of morbid conditions which had nothing intrinsically in common. Of late the term has been employed in a restricted sense to denote a single disease which is pathologically allied to tuberculosis and which affects some of the lower animals, which is transmissible from animal to animal, and which is caused by a bacillus which is not the one that produces tuberculosis. Dr. Klein describes the clinical history and the post-mortem appearances of the disease. Guinea-pigs, rabbits, and mice were the chief animals used in the experiments and in these animals it was found that the disease ran a more rapid course than tuberculosis. The pathological similarity between tuberculosis and pseudo-tuberculosis was seen to be very close, but giant cells were usually absent from the necrosed tissue in the latter disease. Dr. Klein's paper is illustrated by coloured plates and by a large number of micro-photographs. The plates illustrate the morbid naked-eye appearance of the liver and spleen permeated by small white nodules and the first plate would readily have passed in the days of our ignorance for a good representation of organs affected by tuberculous disease. The second and third plates show some of the abdominal organs of a guinea-pig similarly affected, and the fourth plate the appearance produced by the growth of the pseudo-tuberculous bacillus on a potato. There are altogether no fewer than 45 illustrative plates. The pathological and etiological knowledge of the disease which has now been acquired will, Mr. Power believes, be of use in facilitating the detection of the disease and in confirming the diagnosis of tubercle in rodents. Dr. Klein gives exact measurements of the bacillus which produced the disease. He has found that its distribution is somewhat wide, for he has detected it in samples of the unfiltered water of the Thames and Lee, in sewage and in sewage effluents, in milk purchased in London shops, and in milk delivered direct from dairy farms before its arrival at the shops. Dr. Klein does not claim finality for the results of all his numerous experiments; of some he says only that they are highly suggestive and that they deserve repetition.

The second report published in Appendix B, which deals with the bacteriology of scarlet fever, gives the result of an elaborate investigation of the subject by Dr. M. H. Gordon Mr. Power in his summary of the results of this work recalls the fact that Dr. Klein studied the question as long ago as the year 1885 in connexion with an epidemic which it was suspected had been produced by contaminated milk. At a later period Dr. Klein and Dr. Gordon made an inquiry into what have been termed "return cases" of scarlet fever. The results of their investigations convinced them that the disease was due to an organism which they named "streptococcus scarlatinæ" and they believed that the infectiveness of the disease "was judged to be parallel with the presence or with the persistence in the patient's throat" of this micro-organism. The controversy which was raised on the bacteriology of scarlet fever will not have been forgotten. Its general result, Mr. Power says, was that "the conclusions of the Board's investigations were not generally accepted." The fact that streptococci are "morphologically and biologically unstable" makes the differentiation of them "largely a matter of personal equation." In these circumstances it was thought well to commission Dr. Gordon to make a general study of streptococci and to find out how differing conditions altered their biological character. This laborious investigation occupied Dr. Gordon for over two years, and the results of his work certainly deserve careful study. The general conclusions at which he arrived are as follows. 1. Streptococcus scarlatinæ or conglomeratus is a special pathogenic micro-organism distinct from streptococcus pyogenes on the one hand, and from bacillus diphtheriæ on the other. 2. It occurs in the mucous secretion on the surface of the tonsil and fauces in scarlet fever and may persist there in some cases up to a period considerably after the date of attack. 3. It has not been found in four inflamed non-scarlatinal throats examined for it, but on the contrary other virulent streptococci were present in these cases. 4. It may be present in the nasal discharge of scarlet fever. It has not as yet, however, been detected in the aural discharge of that disease. 5 It penetrates the system and can be obtained in pure culture from a serous effusion occurring as a complication in the course of scarlet fever. 6. It may be present in the blood and tissues in fatal cases of scarlet fever and may not infrequently be obtained in pure culture from these sources. 7. The characters of streptococcus scarlatinæ, as isolated from the tonsil of a mild but typical case of scarlet fever, are apt to undergo modification in the tissues of a mouse, and similar modification is found in the case of streptococci obtained from the tissues of a human being in a fatal case. In each instance this modification usually comprises increase of virulence accompanied by diminution of those morphological and cultural characteristics that distinguish the streptococcus scarlatinæ from the streptococcus pyogenes, though close examination shows that sufficient differences exist still to permit identification. The results of Dr. Gordon's observations and experiments, he thinks, "strongly support the view that streptococcus scarlatinæ is the specialised and essential agent of the specific infection known as scarlet fever." In a footnote he adds that "how far streptococcus scarlatinæ merits the epithet specific is a matter for future investigation to decide. The term is for the present better avoided."

Of the other reports contained in Appendix B, three are by Dr. A. C Houston, two by Dr. Klein, and one, containing a preliminary account of the results on bacterioscopic analyses of different cereals and food stuffs, is the result of the researches of Dr. Klein and Dr. Houston. The last report (Appendix 10) records the observations of Mr. H. S. Fremlin on the bacteria found in calf lymph during the process of glycerination. In the order of the frequency of their occurrence it was found that the staphylococcus pyogenes aureus headed the list (500), the staphylococcus pyogenes albus came second, and an unnamed bacillus was third. The effects of glycerine in the various organisms are described in detail and Mr. Fremlin is continuing his researches on the bacteriology of calf lymph, a subject of no small importance in these days of the conscientious objector to vaccination.

Dr. Houston's report on the value of the examination of water for streptococci and staphylococci with a view to the detection of its recent contamination with animal organic matter is of interest to all those who are concerned in the quality of the water supplied to towns from sources which are open to such pollution. The report now published (Appendix B, No. 3) describes Dr. Houston's more recent experiments in a matter which has previously engaged his attention. The general deductions which he draws as to the information really required in the bacteriological analysis of water are as follows. 1. It is a matter of the first importance to have a thorough knowledge of the kind of bacteria which are entitled to be considered "essentially of animal outcome." 2. Accurate knowledge is desirable as to the microbes found in water which are related to morbid processes in man. 3. It is desirable to distinguish between bacterial tests which indicate quite recent pollution from those which indicate less recent pollution, and again to distinguish the latter from those tests which indicate pollution of remote origin (for recent pollution is presumably especially dangerous and pollution of remote date indicates potential rather than actual danger). 4. The presence of the bacillus coli whether in the soil or in water implies recent pollution. For an account of the experiments the article itself must be referred to, but it may be mentioned in passing that the water of the river Brent and that of the Regent's Park Canal received attention. A note appended to Dr. Houston's report refers to the value of a method of research which it may be hoped will receive the attention it deserves as a rough test for indicating the extent to which biological purification has been carried in the case of sewage effluents and of polluted rivers.

---

[1] No. I. was published in The Lancet of June 15th, 1901, p. 1705.

Dr. Houston reports also on the chemical and bacteriological examinations of the washings of soils with reference to the amount and nature of the organic matter and the number and character of the bacteria contained in them (Appendix A, No. 4). This article gives an account of further researches on a subject dealt with in two previous Supplementary Reports of the Medical Officer of the Local Government Board (Appendix B, No. 5, 1898–99, and Appendix B, No. 2, 1897–98). The more recent work consisted of chemical and bacteriological examinations of the washings of soils. The soils, amongst others, which were examined were taken from sewage farms, virgin soil, and the mud of the Thames and of the Brent. The chemical methods adopted in the investigation were those used for the determination of the amount present of free ammonia, albuminoid ammonia, and for the estimation of the amount of oxygen absorbed from permanganate. Biologically the soil waters were examined for the determination of the total number of bacteria, for the spores of aerobic bacteria, for the bacillus coli communis, for the bacillus enteritidis sporogenes (of Klein), and for streptococci.

The conclusions at which Dr. Houston arrives at the end of his three years' inquiry are that soils containing a large proportion of vegetable organic matter, a small proportion of inorganic substances, and little or no animal matter often contain more albuminoid ammonia and absorb more oxygen from organic matter than do soils which contain a large proportion of inorganic substances, and a small proportion of vegetable organic matter, but which are saturated with animal matters of excremental origin. "Washings" from soils enormously and dangerously polluted might contaminate water. This pollution might be chemically inappreciable, yet a like contamination would yield to bacterial examination unequivocal proof of its objectionable origin. The chemical distinction between animal and vegetable organic matter is in great part conjectural in character and fails to define the relative proportions of the different kinds of organic matter present in a substance. Virgin soils do not contain spores of the bacillus enteritidis sporogenes nor of the bacillus coli, nor do they contain streptococci in large numbers. Soils polluted with animal organic matter contain spores of the bacillus enteritidis sporogenes in great quantity. They contain also bacillus coli and streptococci if the contamination be of recent date. The total number of bacteria found in virgin soils is much smaller than that found in polluted soils. The recent derivation of a water from the "washings" of soils can readily be detected by the presence in it of soil microbes and by the large number of spores of aerobic bacteria which it contains.

The inference which Dr. Houston suggests should be drawn from these facts is "that chemistry cannot always be relied on to detect in a water-supply the presence of 'flood water,' much less of 'flood water' of objectionable or dangerous sort, but that bacteriology is capable of appreciating admixture of 'flood water' in comparatively small amount. The presence or absence of spores of the bacillus enteritidis sporogenes further enables the bacteriologist to draw a distinction between 'flood water' derived from soils at one time or another polluted with excremental matters and that which has come from soils free from present or past contamination of objectionable sort. Lastly, the presence or absence of the bacillus coli (or closely allied microbes) and of streptococci allows the bacteriologist to say whether there is or is *not* trustworthy evidence that the 'flood water' has been derived from soils recently polluted with matters of animal outcome."

Dr. Sidney Martin gives a further report on the growth of the typhoid bacillus in soil (Appendix B, 5). The paper has the distinction of being concise, clear, and well written. The experiments conducted by Dr. Martin, as Mr. Power points out, mark a distinct advance in our knowledge of the subject. The results arrived at are the following. 1. Certain cultivated soils, especially garden soils, when sterilised are favourable to the vitality and growth of the typhoid bacillus. Under comparable conditions other virgin or uncultivated soils do not support the bacillus, which rapidly dies. A previously virgin soil which had recently come under grass was found when sterilised to support the life of the bacillus for a certain period but not nearly so long as the more definitely cultivated garden soils. 2. When the typhoid bacillus is added to unsterilised soils, kept very moist and at a temperature of from about 19° to 37° C. it has not been possible to recover it from the soil even after a short period. If, however, the soil be kept in a drier condition and at a low temperature (from 2° to 12° C.) the bacillus can be regained after a certain interval which in these experiments did not exceed 12 days. After this it appeared to die out. 3. The reason of the disappearance of the typhoid bacillus from the unsterilised soils appears to be the antagonism of some of the soil micro-organisms to its growth, and there is some evidence to show that, under the conditions of experiment, the disappearance of the bacillus has taken place *pari passu* with an increase in the number of the putrefactive bacteria. 4. As far as is known the typhoid bacillus has no spores, so that if it once dies it cannot be expected to reappear, unless a fresh inoculation occurs.

The next report is by Dr. Houston and gives an account of a chemical and bacteriological examination of soil obtained from the "fever" and "non-fever" areas at Chichester (Appendix B, 6). It will be more convenient to refer to this paper in connexion with the very able and exhaustive report of Dr. T. Thomson and Colonel Marsh on the prevalence of enteric fever in the city of Chichester.

Dr. Klein's investigation on cockles as the distributing agents of infectious disease (Appendix B, 7) showed that cockles are capable of taking into their interior the microbes of sewage. He found also that raw cockles bought in their shells from a street hawker contained specimens of the bacillus coli and of virulent bacillus enteritidis sporogenes. The report is a preliminary note on a very important inquiry, one part of which is to determine the behaviour of the typhoid bacillus in cockles kept in water polluted with the "material of the typhoid fever."

Dr. Klein's report on the behaviour of certain pathogenic microbes in milk, cream, and cheese (Appendix B, 8) shows that at certain temperatures the tubercle bacillus grows in milk, in cream, and in cheese; that the typhoid bacillus grows in milk and in cream, but not in cheese; that the diphtheria bacillus grows in milk, but not in cream or in cheese: and that the streptococcus scarlatinæ grows well in milk and does not grow well in cream or in cheese. Some interesting points in regard to the growth of the tubercle bacillus were discovered in the course of the experiments.

Dr. Klein and Dr. Houston give a preliminary account of the results of a bacteriological analysis of different cereals and food stuffs. Wheat, oats, rice, and flour from various sources were examined (Appendix B, 9). A number of micro-organisms were discovered, but with the exception of that ubiquitous organism the bacillus enteriditis sporogenes it is comforting to know that they were non-pathogenic.

THE ANNUAL DINNER OF THE ROYAL ARMY MEDICAL CORPS.

THE annual dinner of the Royal Army Medical Corps was held at the Whitehall Rooms of the Hôtel Métropole on Monday, June 17th. Considering the number of officers who are absent on service in South Africa there was a very good attendance, though, of course, the senior members of the service predominated. Surgeon-General J. Jameson, C.B., late Director-General, presided and gave the Royal toasts which were loyally and cordially honoured. He then proposed "The Guests" and alluded to the presence of the civil consulting surgeons who had rendered them such excellent aid in South Africa, pointing out that in affording help in a time of strain to their country they had not only temporarily to break their home ties but also to run many of the risks of war—in fact, one of them, the late lamented Sir W. Stokes, met his death out there He then referred to Sir W. Mac Cormac ("a tower of strength"), Sir F Treves, Mr. Makins, Professor Chiene, Mr. Watson Cheyne, Mr. Lenthall Cheatle, and others. The speaker mentioned the fact that lately he had seen two German attachés who were in South Africa during the war, and on asking them if they could suggest any improvements with regard to our medical service received the reply, "We have *nothing* to suggest"; he also referred to a gentleman from St. Petersburg who said that they greatly admired the medical service and that was the only English service which they did admire. In submitting the toast of "The Guests" he emphasised the great value of the moral support which they had received from the civil consulting surgeons and assured them that the Royal Army Medical Corps cordially congratulated them on the honours which they had so worthily won.

The toast was responded to by Sir **WILLIAM MAC CORMAC**, who bore testimony to the excellent work done in South Africa by the Royal Army Medical Corps, saying that from a considerable experience in other wars as well as in the present one he had no hesitation in saying that the work done by the Army Medical Service in South Africa was as good as, if not even better than, that which had distinguished them in any previous campaign or any similar work in other countries. At the present moment China offered an object lesson of this, for there our Medical Service was admittedly superior to that of our allies. Referring to the difficulties caused by the undermanning of the Royal Army Medical Corps he said that revolutionary changes were often fraught with evil, and in the present instance did not seem to be required. The all essential matter was to procure a sufficiency of men to fill the vacancies in the corps. What was chiefly needed on the part of the authorities and the outside world generally was a much larger measure of sympathy and appreciation for good work well done and without regard for self. The large number of civilian surgeons, some 700 in number, who had served in South [illegible] this. They had witnessed the devotion [illegible] y Medical Corps, which would serve to promote the solidarity between the two branches of the profession.

Sir **FREDERICK TREVES** said that in replying to this toast he had to invert the usual order and refer to the hosts rather than to the guests. He bore tribute to the kindness which had been experienced by the consulting surgeons at the hands of every member of the Royal Army Medical Corps. He then referred to the criticism which had been directed against the Army Medical Service and described it as being in many particulars unfair and un-English, and said that Sir William MacCormac and he had taken the earliest opportunity on their return to England of expressing their high opinion of the services of the Royal Army Medical Corps. He referred to the services of Surgeon-General Jameson at headquarters at home and said that he had every single detail of the department at his finger-tips. In South Africa itself he was surprised to find how wonderfully the work was done, seeing that surgery in war was attended with all sorts of difficulties and not to be conducted as it was at home in a hospital. In passing he mentioned the pleasure it was to civil surgeons to serve under Colonel Stevenson. He referred to the great abilities of Sir Thomas Gallwey in Natal as an organiser and remarked that he had become an expert in the art of commandeering. Lieutenant Colonel Babtie, V.C., too, was noticeable for his powers of organisation, whilst the splendid deed performed by him at Colenso would cause his name to live in history. He mentioned the services at Durban of Major MacCormack and at Pietermaritzburg of Major Dodd. In conclusion, he observed that to obtain a proper estimate of the work of the Royal Army Medical Corps the opinions of two classes should be sought—namely, of the civil surgeons and of the sick and the wounded. He could only say that any corps would be proud of that testimony—testimony borne, be it remarked, by the people who really knew.

Professor **CHIENE** endorsed all that had been said by Sir William MacCormac and Sir Frederick Treves and said that the work that he had seen done as he passed through Wynberg, Kimberley, Mafeking, Johannesburg, and Pretoria was work equal to that done in any civil hospital, and as to the criticisms which had been directed against the medical service all that he could say was that he simply did not understand it. The work done by the Royal Army Medical Corps was work that no civil surgeon could be ashamed of. "We do not believe a word said against you," remarked Professor Chiene. He then proceeded to allude to the enormous difficulties that beset them and the way in which they had been met, and added that the work out there had been well done because Surgeon-General Jameson was at the head of affairs at home. He had come that day from Edinburgh to be present at the dinner in order to support Surgeon-General Jameson and to indicate on behalf of the profession in Scotland their opinion of his work.

Surgeon-General **O'DWYER** then proposed the health of Surgeon-General Jameson, a toast which was most warmly received and greeted with musical honours.

Surgeon-General **JAMESON**, in reply, thanked the officers and guests for the cordial way in which they had received him. He referred to the difficulties of the campaign and bore tribute to the excellent assistance which he had received from his colleagues at headquarters. "Never," he said, "had a Director General been better served." As to the future he had little fear; they would work out their own salvation. The alterations that were needed could be counted on a man's fingers; but one thing was indispensable: the *personnel* must be increased and to that end the service must be rendered attractive. There was the whole pith of the matter. It was also desirable that more sympathy should be extended to them from outside Although he had no longer official connexion with the Army Medical Service he could assure them that his interest in the department would never cease, and he felt confident that the cloud which had so suddenly arisen and was now hanging over them would as suddenly disappear.

During the evening the band of the Royal Army Medical Corps played an excellent selection of music.

THE ANNUAL DINNER OF THE INDIAN MEDICAL SERVICE.

THE annual dinner of the Indian Medical Service was held at Princes Restaurant, Piccadilly, London, W., on June 13th, Surgeon General R. Harvey, C B, D S O, Director-General of the Service, being in the chair. There was a good attendance which doubtless would have been even better had it not been for the trying circumstances through which India has lately been passing—plague, famine, and the wars in China and South Africa having made heavy claims upon the services of Indian medical officers.

The usual loyal toasts having been given by the Chairman and duly honoured, "The Sister Services" was proposed by Surgeon-General Sir Joseph Fayrer, who alluded to the good work that had been done by the services in the South African war and quoted the report of the Royal Commissioners in support of his statements.

Sir Henry F. Norbury, Director-General of the Royal Navy Medical Service, in replying, said that up to the present time there had been at the several examinations a sufficiency of competent candidates, and no gentleman had received a commission as a medical officer in the Royal Navy who had not been considered quite professionally competent by the board of examiners. The war in China had, as far as the medical department of the navy was concerned, at one time been beset with much greater difficulties than it had experienced in South Africa, and in China the way in which the arduous medical work had been carried out had been most favourably reported on by Vice-Admiral Sir E. Seymour, G C B, the Commander-in Chief on that station. Surgeon-General A F. Preston, A M.S, also briefly acknowledged the toast.

"The Indian Medical Service" was then proposed by Surgeon-General Harvey, who said that it would be manifestly improper for him to discuss the various schemes for the improvement of the medical services that were at once to be, or had been, put forward These schemes would receive the most careful consideration from the Government of India, and he believed that the Service was patriotic enough to accept any changes which might be considered necessary in the real interests of the State. He did not think, however, that any change disastrous to the Service could possibly be in the interests of the State, and he therefore considered that the Service might regard whatever proposals might be put forward with equanimity. As these subjects were tabooed he would say a few words as to certain misconceptions which seemed to exist as to the conditions in the Service itself and the relations of the Government of India to the Service. There was said to be much discontent in the Service, but this was mainly due to the one great grievance—the constant interference with leave. Steps had been taken to remedy this and he thought that most of the other grievances were more or less imaginary. A complaint had recently appeared in a medical journal that the pay on entry to the Service was

286 rupees. A statement of this kind, if true, would tend to make good men hesitate to enter the Service, and he could not conceive what good the author of it expected to gain by appealing to the papers instead of representing the matter to his departmental superior. The statement, however, was the reverse of true, for the minimum was raised from 286 to 317 rupees more than 16 years ago, and further raised to 350 rupees four years ago, so that with this and exchange compensation allowance the pay of the junior officers was some 30 per cent. higher than the amount stated. Another grievance recently put forward was that the pensions of civilians was much larger than those of the Service, but the inventor of this one was probably not aware that every civilian contributed more than half of his own pension, while the medical pensions were given by the State without any contribution from the officers concerned. He had recently been asked whether it was true that medical officers had to act as butlers to their brother officers. This was a very coarse way of expressing the fact that regimental medical officers were frequently asked to be managers of the mess. In all regiments some officer had to do this, and he was proud to say that he had had the honour to be "butler" to the Central India Horse during the greater part of the time he had belonged to the regiment. He had seen a recent complaint that the work of a civil station and the responsibility of a jail were too heavy and exposed a man to risk of having to answer for the misdeeds of his subordinates, but he was glad to think that what most men wanted was the opportunity for hard work and responsibility, and he knew that if they did their work properly subordinate officials would have no chance of involving them in loss. One other point he would like to allude to. Two years ago their secretary had stated that he knew of no instance of a man receiving any proper acknowledgment for distinguished work in the ordinary lines of the profession. That was, unfortunately, true, speaking as he was of purely surgical and medical work, but the six appointments of Honorary Physician and Surgeon to the King were intended to reward such. A gentleman in a medical journal had, however, given a new complexion to the complaint by saying that with the single exception of Dr. D. D. Cunningham no man had ever been rewarded for good professional work. This statement also would tend to deter good men from entering a service where there were no rewards for merit, but in this extended sense it happened to be entirely untrue, since representatives of every other branch of the profession had from time to time been decorated for good work in botany, physiology, hygiene, obstetrics, and gynæcology, medical jurisprudence, college and jail, plague, and famine, work, while a distinguished chemist's name was before the Government for recognition when he unfortunately died, and Mr. Haffkine, who, though not a member of, was in intimate relation with, the Service, had received a C.I.E. for bacteriological work in connexion with cholera and plague. The Government of India was frequently accused of indifference to the interests of the Service and particularly of neglect to further medical research. He had recently read how the perverse imbecility of an administrative pedant had thwarted Major Ronald Ross in his most valuable and distinguished work by taking him away from the scene of his labours and setting him to routine work which anyone else could have done as well. The truth was exactly the other way. The Government of India had taken Major Ross from routine work, put him on special duty to investigate the malaria problem, given him 200 rupees a month additional pay when so employed, and had thus given him the opportunity and the leisure without which his valuable discoveries might not have been completed. They were associating one of their own officers with the envoys sent to India by the Royal Society to investigate Indian fevers, and he hoped it might be found possible to send an officer with Major Ross on his new expedition to Africa. The Government of India had given an allowance which had enabled the committee of which he had the honour to be President to start the Pasteur Institute of India which was doing admirable work. They had started a new alienist department and sanctioned the scheme for research laboratories. The central laboratory would be started at once and the provincial laboratories would follow as funds became available. He thought, therefore, that he had shown that the Government of India was alive to its responsibilities and that the Service held out as good opportunities as ever to good men. He knew of no service in the world which gave so many opportunities of doing good. It gave to its most unfortunate member a reasonable subsistence and a fair pension, while to many of its members it gave good, and to some very valuable, prizes, with the chance of honours and distinctions. He believed that the Service would continue to deserve well of the country in the future as in the past, and he invited them to drink to this most desirable consummation.

"The Guests" was proposed by Dr. W. S. Playfair, and responded to by Dr. F. W. Pavy, who referred humorously to the physiology of dining.

Lieutenant-Colonel Lyon then rose and said that they must not forget to thank Mr. Freyer, who had acted as secretary of the dinner and to whom, indeed, was due the credit for the initiation of the annual dinner of the Indian Medical Service.

Mr. Freyer, in replying, laid stress on what, in his opinion, was a great grievance—namely, that honours were not given as they should be for good work done purely in surgery and medicine which lay at the very foundation of the work of the Service.

During the course of the toast-list Surgeon-General Sir Joseph Fayrer mentioned that a history of the Indian Medical Service was being written by Surgeon-General Beatson.

In the intervals between the toasts the pleasure of the evening was enhanced by Mr. Percy French who sang amusing Irish songs and drew in chalks topsy-turvy pictures which would, we imagine, delight the author of the "Bab Ballads."

The following is a list of the officers and guests present:—

Surgeon-Generals: W. B. Beatson, Sir J. Fayrer, Bart., K.C.S.I., F.R.S., W. R. Rice, C.S.I., and O. Sibthorp, C.B. *Colonels:* W. E. Oates, H. Cayley, D. E. Hughes, J. O. Penny, W. H. Roberts, and D. O. O'O. Raye. *Lieutenant-Colonels:* O. Baker, S. H. Browne, C.I.E., A. Crombie, E. F. H. Dobson, P. J. Freyer, T. J. Greany, P. de H. Haig, D. F. Keegan, Sir George King, K.C.I.E., Sir A. S. Lethbridge, K.C.S.I., I. B. Lyon, C.I.E., R. Macrea, H. McCalman, G. Massy, R. D. Murray, E. Palmer, J. Parker, W. A. Simmonds, J. F. Tuohy, R. R. H. Whitwell, and A. H. Williams. *Majors:* J. W. Caldwell, E. R. W. C. Carroll, T. E. Dyson, F. J. Drury, S. Hassan, and O. T. Hudson. *Captains:* S. Dallas, G. G. Giffard, P. P. Kilkelly, A. E. H. Pinch, and E. E. Waters; and Dr. W. S. Playfair.

Guests: Sir H. F. Norbury, K.C.B., Surgeon-General A. F. Preston, A.M.S., Dr. F. W. Pavy, F.R.S., President of the Royal Medical and Chirurgical Society, Mr. John H. Morgan, F.R.C.S., President of the Medical Society of London, Dr. J. E. Squire, and Mr. Thomas Wakley, jun.

MIDLAND MEDICAL UNION.

A MEETING of the Nottingham branch of the above Union was held at the Masonic Hall, Nottingham, on June 12th, Mr. G. B. WRAY being in the chair.

Mr. O. J. PALMER (Mansfield) reported on the work done in his district. 1. An ironworks club which had proposed to alter its form of payments so that an average pay of from 18*s*. to 20*s*. per accident should be reduced to 15*s*. had been told that its suggestion was not agreeable to the surgeons (18 or 20 in number). The club thereupon gave way and continued the old rate. 2. Most of the friendly societies in the neighbourhood were paying 4*s*. per member and were now being approached with a view to having that fee raised. 3. The guinea midwifery fee was generally adopted except in one or two colliery villages. In the case of Dr. W. C. Rainsbury (Teversall), who had received notice after adopting this fee, another surgeon had been engaged, but there were strong reasons for hoping that Dr. Rainsbury would eventually be reinstated on his own terms.

Dr. E. H. HOUFTON (Shirebrook) said that a similar condition of things was to be reported from Chesterfield. Most of the clubs had been raised to 4*s*. and arrangements were in progress to meet delegates from the friendly societies with a view to a further rise. Dr. Houfton pointed out that one or two of the men who still refused to adopt the guinea midwifery fee (and so stood in the way of others) were men in good position who perhaps charged full fees themselves; but having very large practices they allowed their assistants to take 15*s*. and even 10*s*. 6*d*. Such men could better afford to risk losing a few shillings than many of those who had taken the risk and gained the point.

The following motions (previously passed at Mansfield and Chesterfield) were put from the chair, seconded by Dr. J. H. THOMPSON (Nottingham), and carried unanimously:—

[illegible] objects of the Union.

Dr. W. HUNTER (Nottingham) congratulated the Mansfield and Chesterfield branches on what had been done. It showed that something could be done if men stood together. He thought that further efforts should be made to interest the profession in Nottingham as there were plenty of things to discuss and many matters that could be improved upon by concerted action.

The question of an indemnity fund was next raised. At meetings held recently at Chesterfield and Mansfield it was unanimously resolved that a fund should be commenced for the purpose of fighting to a conclusion the question of the increase in remuneration for contract work, &c., and more particularly for the purpose of aiding financially any of the members who might need such help in consequence of their loyally abiding by the Union. It was further resolved that subscription to this fund should not be compulsory, but that in the case of a member applying to be indemnified from this fund who was not a subscriber to it the granting of any money should be left to the president and vice-president, who should decide whether there were special circumstances entitling such members to relief. It was further resolved that members should be asked to guarantee five guineas, or multiples of five guineas, so that in the event of indemnity being required the money might be called up in the proportion promised. The sums promised up to the present amount to over 300 guineas. Further promises are solicited, but will not be called up unless required.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Southampton Port Sanitary District.—The efficiency of port sanitary administration in the port of Southampton is of special significance at this moment when, bubonic plague being present in South Africa, large numbers of troops are returning from the Cape and the Transvaal to this country and notably perhaps to Southampton. The regulations relative to plague, yellow fever, and cholera drawn up by Mr. A. Wellesley Harris, the medical officer of health, indicate that vigorous steps are being taken at Southampton and that the plague order of the Local Government Board is being liberally interpreted. It seems to be the practice to require all vessels from infected ports to bring up opposite Netley and there to await the visit of the medical officer of health. Moreover, a list of ports regarded as infected is drawn up by this officer and furnished to the Customs officers, pilots, ship-owners, and masters. This is in our view the proper arrangement, and we think that all port medical officers of health should endeavour to bring about similar inspections of vessels from infected ports. The regulations referred to contain, besides the list of infected ports, a concise synopsis of the symptoms of plague in one or another form, a caution as regards rats, directions for obtaining material for cases of suspected plague, a recommendation as to vessels being provided with a supply of Yersin's serum which, in the view of Mr. Harris, is both prophylactic and curative, and, lastly, a recipe for the preparation of a useful disinfecting solution.

Bristol Port Sanitary District.—This annual report might not inappropriately be termed "the rat report," seeing that a large portion of it is taken up with wholesome considerations as to the dangers of allowing rats from "infected" or "suspected" ports to have access to the shore and to hold communication with local rats. Dr. D. S. Davies and Mr. J. O. Heaven, the port medical officers of health, furnish in their report an interesting synopsis of much of the evidence which associates plague in rats with that in the human species. The writers of the report liken plague to typhus fever in respect of infectivity; but although this is an oft-quoted parallel we doubt if the bubonic type of plague at all approaches typhus fever in its infective power. With regard, however, to pneumonic plague a different story has to be told, its power of infectiveness being quite equal, if not above, that of typhus fever in modern days. To revert, however, to the question of rats there is no doubt that the part which they take in the diffusion of plague varies enormously in different outbreaks. In Sydney, as Dr. Davies and his colleague point out, the association of rats with the outbreak of plague in human beings was most marked, but, on the other hand, there is not sufficient evidence to show that either in the case of Oporto or Glasgow were these rodents instrumental in conveying disease. In the report which is now before us a summary is given of the measures of precaution adopted at sundry places in the direction of control of rats. A useful addition might have been made to this information by including the regulations as to ship-berthing which are in force in Melbourne and Sydney. In these regulations the master is required to sign a deed undertaking to fulfil all the conditions if his vessel is allowed to proceed to her berth and immediately to take her out of harbour on request. Among these regulations we note that the vessel is to be kept off from the wharf by means of fenders for a distance of at least four feet; fresh tar is to be applied to each end of the hawser or rope, such tar to be kept moist by repeated applications; all gangways are to be drawn up when not wanted for the discharge of cargo; and the ship's sides are to be well lighted by means of electric or other lights. We notice that Dr. Davies refers to a recommendation by Dr. Calmette that the discharge of cargo, especially grain and cotton, from places where plague exists should be strictly forbidden until the most rigorous inspection has been made. Bales and sacks should be opened and their contents emptied out and examined. "If any dead rats are found the whole must be destroyed without the ship being allowed to touch the quay." This is a far-reaching recommendation on the part of Dr. Calmette and it is difficult to believe that he entirely comprehends the magnitude of it or that he has given such advice without at least ascertaining that the rats died from plague. Dr. Davies himself furnishes a most instructive narrative which admirably illustrates the difficulty of dealing with a vessel thus circumstanced; and it is well that all port medical officers of health should be aware of it. On Jan. 22nd of this year it was reported that six rats had been found dead in the forehold of a vessel which had arrived on Jan. 20th at Bristol from Smyrna, with her crew all well. The vessel at the time of this discovery was discharging a cargo of barley and valonia by the quay-side in the centre of the city. One of the dead rats was examined by a local bacteriologist and the presence of plague was strongly suspected. It was not, however, deemed desirable to take definite action upon this suspicion, and, the watch on the vessel being redoubled and other precautions being taken, the report of the Local Government Board, to whom other rats had been sent, was awaited. On Jan. 27th the fact that the rats were infected with plague was announced by the central Board, and the ship in question was certified as "infected" under the terms of the plague order. Apparently she was sent into mid-stream and her holds were thoroughly fumigated with sulphur. After this the rest of the cargo was discharged and a second fumigation was carried out. The men who had unloaded the ship were kept under observation for 14 days. As Dr. Davies adds, the circumstances connected with this vessel raise some interesting points. Before confirmation of the rat examination three-fourths of the cargo had been discharged. Dr. Calmette would, it seems to us, have recalled this three-quarters and destroyed it, together with the remaining fourth. The Bristol sanitary authority, on the other hand, "disinfected" the remaining fourth, but apparently let the bulk of the cargo go, notwithstanding the fact that it was not improbably interspersed with rat dejecta, some of which may have been specifically fouled. But Dr. Davies acted in the only practicable fashion, and it is perfectly clear that he is as alive as any medical officer of health in this country to the dangers which threaten our ports. Theory and practice, however, are difficult to combine on board ship and in cases where cargoes worth perhaps many thousands of pounds are at stake. As with Southampton, so with Bristol, the medical officer of health has drawn up a list of infected ports. Dr. Davies and Mr. Heaven, whose report is most interesting, supply a map of the world showing the places where plague has occurred since January, 1899.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6203 births and 3189 deaths were registered during the week ending June 15th. The annual rate of mortality in these towns, which had been 16·7, 16 3, and 15·2 per 1000 in the three preceding weeks, further declined last week to 14·5 per 1000. In London the death-rate was 13 7 per 1000, while it averaged 15 1 in the 32 large provincial towns. The lowest death-rates in these towns were 8 5 in Croydon, 9 5 in Cardiff, 9 8 in Derby, and 10 4 in Portsmouth; the highest rates were 19 4 in Preston, 20·5 in Sunderland, 22 6 in Swansea, and 22 7 in Gateshead. The 3189 deaths in these towns last week included 357 which were referred to the principal zymotic diseases, against 387, 361, and 320 in the three preceding weeks; of these 114 resulted from measles, 78 from whooping-cough, 61 from diarrhœal diseases, 41 from diphtheria, 39 from scarlet fever, and 24 from "fever" (principally enteric). No death from any of these diseases was registered last week either in Plymouth, in Norwich, in Derby, or in Huddersfield; in the other towns they caused the lowest death-rates in Cardiff, Burnley, and Newcastle, and the highest rates in West Ham, Swansea, Wolverhampton, Bolton, and Gateshead. The greatest mortality from measles occurred in West Ham, Birmingham, Wolverhampton, Bolton, and Gateshead; from scarlet fever in Preston; from whooping-cough in Swansea, Wolverhampton, and Gateshead; and from diarrhœal diseases in Wolverhampton and Blackburn. The mortality from "fever" showed no marked excess in any of the large towns. The 41 deaths from diphtheria included 13 in London, four in Liverpool, four in Salford, and four in Leeds. No fatal case of small-pox was registered last week in any of the 33 large towns; only one small-pox patient was admitted into a Metropolitan Asylums hospital during the week, and one remained under treatment on Saturday last, June 15th. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2594, against numbers increasing from 1522 to 2462 on the seven preceding Saturdays; 323 new cases were admitted during the week, against 341, 317, and 314 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 240 and 187 in the two preceding weeks, further declined last week to 159, and were 68 below the corrected average. The causes of 31, or 1·0 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Bristol, Nottingham, Salford, Hull, and in 13 other smaller towns; the largest proportions of uncertified deaths were registered in Wolverhampton, Liverpool, Halifax, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 20 7, 20·1, and 19 6 per 1000 in the three preceding weeks, further declined to 16 9 per 1000 during the week ending June 15th, but showed an excess of 2·4 per 1000 over the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 12 5 in Aberdeen and 15 7 in Paisley to 17·8 in Glasgow and 19 8 in Greenock. The 539 deaths in these towns included 32 which were referred to whooping-cough, 17 to measles, 17 to diarrhœa, three to scarlet fever, three to diphtheria, and three to "fever." In all, 75 deaths resulted from the principal zymotic diseases last week, against 94, 97, and 102 in the three preceding weeks. These 75 deaths were equal to an annual rate of 2·4 per 1000, which was 0·8 above the zymotic death-rate last week in the 33 large English towns. The fatal cases of whooping-cough, which had been 40, 47, and 48 in the three preceding weeks, declined again last week to 32, of which 16 occurred in Glasgow, nine in Edinburgh, three in Dundee, and two in Paisley. The deaths from measles, which had been 17 and 21 in the two preceding weeks, declined agai to 17 last week, and included nine in Glasgow, tw in Edinburgh, two in Dundee, and two in Greenocl The fatal cases of diarrhœa, which had been 30, 2 and 18 in the three preceding weeks, further decrease last week to 17, of which nine were registered in Glasgo and five in Edinburgh. The deaths referred to different form of "fever," which had been three and six in the two preceding weeks, declined again to three last week and a occurred in Glasgow. The mortality from diphtheria showe a slight decline from that recorded in recent weeks, whil that from scarlet fever was slightly in excess. The death referred to diseases of the respiratory organs in these towns which had been 107 and 98 in the two preceding week rose again last week to 101, and were equal to the numbe in the corresponding period of last year. The causes of 31 or nearly 6 per cent., of the deaths in these eight towns las week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 24 3 21·3, and 20 0 per 1000 in the three preceding weeks, furthe declined to 19 6 per 1000 during the week ending June 15th During the past four weeks the death-rate in the city ha averaged 21·3 per 1000, the rates during the same period bein 14·7 in London and 20·3 in Edinburgh. The 141 deaths o persons belonging to Dublin registered during the week unde notice showed a decline of three from the number in th preceding week, and included eight which were referred t the principal zymotic diseases, against five and nine in th two preceding weeks; of these, four resulted from diarrhœa, three from whooping-cough, and one from "fever." These eight deaths were equal to an annual rate o 1·1 per 1000, the zymotic death-rates during the same period being 1·6 in London and 2 9 in Edinburgh. The mortality from diarrhœa showed a marked increase upon that recorded in any recent week, while the deaths from whooping-cough, which had been five, two, and five in the three preceding weeks, declined again last week to three. The 141 deaths in Dublin last week included 27 of children under one year of age and 40 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight excess on the numbers in the preceding week. Nine inquest cases and six deaths from violence were registered, and 39, or more than one-fourth, of the deaths occurred in public institutions. The causes of 12, or nearly 9 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING MAY, 1901.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in each of the 29 cities and boroughs in the county of London. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 8·5 per 1000 of the population, provisionally estimated at 4,543,757 persons in the middle of the year. In the three preceding months the rates had been 5·8, 5·3, and 5 2 per 1000 respectively. The rates were considerably below the average in Kensington, the City of Westminster, Stoke Newington, Wandsworth, and Woolwich; while they showed the largest excess in Fulham, Hackney, Finsbury, Shoreditch, and Bethnal Green. Three cases of small-pox were notified in London last month; of these, one belonged to St. Marylebone, one to Islington, and one to Bethnal Green. One small-pox patient was admitted into a Metropolitan Asylums hospital during the month, and remained under treatment on Saturday, June 1st. Scarlet fever was excessively prevalent last month; among the various metropolitan boroughs this disease showed the greatest proportional prevalence in Fulham, Finsbury, the City of London, Shoreditch, and Bethnal Green. The Metropolitan Asylums hospitals contained 2291 scarlet fever patients at the end of May, against 1791, 1533, and 1491 at the end of the three preceding months; the weekly admissions averaged 339, against 156, 142, and 179 in the three preceding months. The prevalence of diphtheria also showed a marked increase over that recorded in recent months; this disease was proportionally most prevalent in Hackney, Shoreditch, Bethnal Green, Poplar, and Deptford boroughs. There were 1101 diphtheria patients

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated population in the middle of 1901.	Notified Cases of Infectious Disease. Small pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers. * Including membranous croup.

under treatment in the Metropolitan Asylums hospitals at the end of May, against 1111, 1084, and 960 at the end of the three preceding months; the weekly admissions averaged 160, against 136, 134, and 117 in the three preceding months. Enteric fever was slightly more prevalent last month than in the preceding month; among the various metropolitan boroughs the greatest proportional prevalence of this disease occurred in Fulham, City of Westminster, Shoreditch, Poplar, and Greenwich. The number of enteric fever patients under treatment in the Metropolitan Asylums hospitals, which had been 224, 162, and 121 at the end of the three preceding months, had further declined to 95 at the end of May; the weekly admissions averaged 14 last month, against 25, 18, and 16 in the three preceding months. Erysipelas was proportionally most prevalent in St. Marylebone, Hackney, Holborn, Shoreditch, and Greenwich. The 29 cases of puerperal fever included five in Stepney, four in Islington, and three in Paddington.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in the public institutions of London having been distributed among the various boroughs in which the deceased persons had previously resided. During the five weeks ending June 1st the deaths of 6702 persons belonging to London were registered, equal to an annual rate of 15·4 per 1000, against 19·8, 18·2, and 17·6 per 1000 in the three preceding months. The lowest death-rates last month in the various metropolitan boroughs were 10·3 in Hampstead, 11·2 in Stoke Newington, 11 6 in Wandsworth and in Lewisham, and 12·6 in Paddington and in Battersea; the highest rates were 18·5 in Stepney, 18 8 in the City of London, in Shoreditch, in Poplar, and in Southwark, 19·3 in Bermondsey, and 22·1 in Finsbury. During the five weeks of May 718 deaths were referred to the principal zymotic diseases; of these, one resulted from small-pox, 202 from measles, 75 from scarlet fever, 90 from diphtheria, 249 from whooping-cough, 24 from enteric fever, 77 from diarrhœal diseases, and not one either from typhus fever or from any ill-defined form of continued fever. No deaths from any of these diseases occurred last month in the City of London; among the various metropolitan boroughs they caused the lowest death-rates in Kensington, Hampstead, Stoke Newington, Lewisham, and Woolwich, and the highest rates in *Fulham, Bethnal Green*, Poplar, Southwark, and Bermondsey. The fatal case of small-pox was that of a person belonging to Bethnal Green. The 202 deaths from measles showed a decline of 178 from the average number in the corresponding periods of the 10 preceding years; this disease was proportionally most fatal in Chelsea, Poplar, Southwark, Deptford, and Greenwich. The 75 fatal cases of scarlet fever slightly exceeded the corrected average; among the various metropolitan boroughs the greatest proportional mortality from this disease occurred in Shoreditch, Bethnal Green, Poplar, Bermondsey, Camberwell, and Deptford. The 90 deaths from diphtheria were only about one-half of the corrected average number; this disease was proportionally most fatal in Paddington, Hackney, Finsbury, Bethnal Green, and Holborn. The 24 fatal cases of "fever" showed a marked decline from the average number in the corresponding periods of the 10 preceding years; the highest "fever" death-rates occurred in the City of Westminster, Islington, Stepney, and Bermondsey. The 77 deaths from diarrhœal diseases were almost equal to the average number; these diseases were proportionally most fatal in Fulham, Holborn, Finsbury, and Woolwich boroughs. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during May was nearly 29 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 112 per 1000. The lowest rates of infant mortality were recorded in Paddington, the City of Westminster, St. Marylebone, Holborn, Wandsworth, and Lewisham; and the highest rates in Chelsea, Finsbury, Shoreditch, Bermondsey, and Camberwell.

A TABLET placed in the Church of St. Andrew, Holborn, in memory of the late Dr. William Marsden, the founder of the Royal Free Hospital, was unveiled on Wednesday last by Archdeacon Sinclair. The tablet, which is set in one of the panels on the right of the entrance to the church, is the gift of the Cordwainers' Company.

METROPOLITAN HOSPITAL SUNDAY FUND.

THE following is a record of some of the principal amounts that have been received in aid of the Fund up to the time of going to press on Thursday. The total sum then amounted to £25,000. At the corresponding period last year the total was £24,000:—

THE SERVICES.

Royal Navy Medical Service.

Fleet Surgeon Thomas Desmond Gimlette has been promoted to the rank of Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

Surgeon P. T. Sutcliffe is appointed to the *Niobe*.

Royal Army Medical Corps.

Albert Stanley Knight Prescott, Deputy Surgeon-General, retired list, has been selected for medical charge of troops at Gravesend. Captain O. T. Samman joins at Woolwich. Captain *O. B. Lawson* proceeds to Dover for duty. Lieutenant-Colonel Matthew D. O'Connell to be Colonel, vice C. F. Churchill, retired. Lieutenant-Colonel J. D. Day retires on retired pay.

India and the Indian Medical Service

The King has approved of the following promotions among the officers of the Indian Medical Service:—Majors to be Lieutenant-Colonels: *Bengal Establishment:* Frederic Daly Cæsar Hawkins, John Adams Cunningham, Alexander Silcock, Patrick Mullane, John William Rodgers, and James Farquharson Maclaren. *Madras Establishment:* Arthur Theophilus Lodge Patch, Charles Adams, Jamshedji Kharshedji Kanga, and Alfred James O'Hara. *Bombay Establishment:* Alexander Milne, Richard John Baker, William Alfred Corkery, and Sarkies Thaddeus Avetoom. Captains to be Majors: *Bengal Establishment:* Fairlie Russell Ozzard, Adam Rivers Steel Anderson, John Telfer Calvert, Edgar Jennings, and Arthur Gervase Hendley. *Bombay Establishment;* William Symonds Percival Ricketts, Charles Malcolm Moore, George William Jenney, and Charles Tilson Hudson.

The King has also approved of the retirement from the Service of the undermentioned officers: *Madras Establishment:* Lieutenant-Colonel Arthur Henry Leapingwell and Lieutenant-Colonel Francis Joseph Doyle. *Bombay Establishment:* Colonel Samuel O'Brien Banks, Lieutenant-Colonel Mathew Lorenz Bartholomeusz, and Lieutenant-Colonel Joseph Parker.

Militia Medical Staff Corps

Samuel Thomas Beggs to be Surgeon-Lieutenant.

Imperial Yeomanry.

Cheshire (Earl of Chester's): Surgeon-Captain G Harrison signs his commission, with permission to retain his rank id to wear the uniform of the regiment on retirement erbyshire: Surgeon-Captain C. H. Hough resigns his mmission and is granted the rank of Surgeon Major, ith permission to retain his rank and to wear the uniform the regiment on retirement.

Volunteer Corps.

Rifle: The Queen's Rifle Volunteer Brigade the Royal cots (Lothian Regiment): Brigade-Surgeon-Lieutenant-olonel C. W. MacGillivray resigns his commission, with perission to retain his rank and to wear the uniform of the orps on retirement, vacating at the same time the appointent of Senior Medical Officer to the Forth Volunteer fantry Brigade. 3rd (Dumfries) Volunteer Battalion the ing's Own Scottish Borderers. Surgeon-Captain J. aclachlan to be Surgeon-Major. 1st (Pembrokeshire) olunteer Battalion the Welsh Regiment: William Starbuck riffith to be Surgeon-Lieutenant. 1st Volunteer Battalion e Northamptonshire Regiment: Surgeon-Lieutenant J llison to be Surgeon-Captain. 3rd (Buchan) Volunteer attalion the Gordon Highlanders: Robert John Cheves to e Surgeon-Lieutenant.

Volunteer Medical Staff Corps.

The Woolwich Companies: John Hardie to be Surgeon-ieutenant

Volunteer Infantry Brigade.

Glasgow: Surgeon-Lieutenant-Colonel J. Macfie, 4th Volunteer Battalion the Cameronians (Scottish Rifles) to be Brigade-urgeon-Lieutenant-Colonel on appointment as Senior Medical fficer to the Brigade.

South African War Notes.

In the official list of casualties which occurred at Vilmansrust on June 12th among the list of killed appears he name of Surgeon-Lieutenant H. A. Palmer, 5th Victorian Mounted Infantry.

The following are reported to be slightly improved:—Civil Surgeon Wilbond and Civil Surgeon Graham (June 14th).

The following officer has been discharged from hospital to duty: Civil Surgeon C. Lindsay Dunn The following officers are on passage home: Major J. H. Greenway, R A M C, Major A. E Tate, R.A.M C, and Civil Surgeons L E. Owen, G. H. Bristow, R Lindsay, F. B. Stewart, R. Whittington, and W. R Griffin.

Mrs. Skey Muir, the honorary secretary of the Royal Army Medical Corps South Africa Fund, and Mrs. Charters Symonds, the honorary treasurer, have issued an appeal for contributions to enable them to send a final consignment of comforts to the men of the Royal Army Medical Corps in South Africa who still number over 4000. Contributions will be gladly received by Mrs Charters Symonds, 58, Portland-place, W.

Army Affairs in South Africa.

The war news from South Africa is of a somewhat mixed character. On the one hand there has been severe fighting with De Wet's force near Reitz followed by its defeat with the capture of a convoy of stores, ammunition, vehicles, and horses by General Elliot's column; and, on the other hand, the surprise of a detachment of Victorian Mounted Rifles detached from General Beatson's column, by the Boers near Middleburg in the Transvaal with the capture of two guns and severe loss to the Australians. Taken altogether the most recent war news is not of special importance, but the results are, on the whole, favourable to the British and show that the usual captures of prisoners, stock, and ammunition are still going on and that the opposition and strength of the Boer forces are being slowly but surely worn down. They carefully avoid all general engagements or fighting on any large scale. The list of casualties in the recent fighting is a heavy one considering the small size of the forces engaged and there is still the chronic drain going on from disease-causes. Some cases of bubonic plague have been recently reported from Port Elizabeth, Maitland, and Simonstown. The total number of cases hitherto reported from South Africa has been 714, of which 318 have terminated fatally. What most people regard as the most disquieting news does not come from South Africa or abroad, but has its origin in this country, and is of a political and manifestly party character. The movement to which we allude is one of limited extent and so far as it is of a purely political nature it does not concern us, but as a matter of common sense we cannot shut our eyes to the injurious effect it is likely to have at the present time. No one is likely to accuse us of being unmindful of the sufferings of those who are detained or sheltered in the various camps of refuge in South Africa. In common, we suppose, with everyone else, we deeply regret the hardships, sickness, and other evils that have been brought upon a number of innocent women and children, but surely Mr Kruger and those who sided with him and were instrumental in bringing about this war should have thought of all that beforehand and are responsible for it? To read much of what is being put forward at the present time it might be supposed that Mr Kruger and his allies had never made any preparations for this war; that they had not delivered an ultimatum couched in the most peremptory terms and immediately followed it up by invading the late Queen's territory; and that the late President of the Transvaal Republic, after having involved his unfortunate country in all this misery and distress, had not consulted his own personal safety and interests and fled, leaving his suffering and ruined people and his wife to take care of themselves. Rightly or wrongly there are a good many people in South Africa and at home who think that but for the humanity, merciful consideration, and leniency with which the Boers and their families have been treated in the past, the war would have been over long ago. The task of providing for all the women and children is one of enormous difficulty and candour compels us to say that it would be about as just to blame the Government of this country for the present exceptional weather as to blame them for an outbreak of measles [illegible] refugee camps or, under the circumstances, [illegible] children [illegible] the empire, who have been [illegible] the campaign, [illegible] g all the [illegible] including suffering and hardships of the campaign, [illegible] want of food, for nearly two years to find that the sympathies of some of their countrymen are, after all, apparently with the Boers This war in South Africa has, indeed, been unique in a good many respects; in addition to its having been throughout a fight with physical geography as well as with an astute and stubborn foe. It has been the graveyard not only of innumerable humane and brave soldiers but of many *military reputations and a source of keen* disappointment to the medical service. But things will and must right themselves in the end, justice will be done, and the right-thinking, who happily form the large but silent majority, will see that it is done when they have the opportunity *of declaring their opinion.*

Hæmostasis on Active Service.

In an original article bearing evidence of great research, which was published in the *Archives de Médecine et de Pharmacie Militaires* for March and the two following *months, Surgeon-Major Moingeard treats of hæmorrhage on* active service and the means for most effectually controlling it. It is the *writer's object "to demonstrate on the* one part the procedures which are the most simple, and on the other those which under the circumstances of a campaign could be employed with the greatest certainty." Some of the older authorities maintained that deaths from hæmorrhage on the field of battle were of infrequent occurrence, whereas others *said that three-fourths of the fatalities were* due to it. According to the Crimean statisticians primary hæmorrhage was responsible for 18 per cent. of the deaths *during an action, and Chenu* has placed the same proportion on record for the war of 1870. On the introduction of the modern rifle with its small hardened projectile the general belief was that hæmorrhage would attend on gunshot wounds with greater frequency than before, but in the opinion of Surgeon-Major Moingeard such has not proved to be the case. In the late Spanish-American war La Garde found that hæmorrhage was comparatively rare after *gunshot injuries. Secondary* hæmorrhage, according to Surgeon-Major Moingeard, is of two kinds. In the *first* variety the fibrino-globular plug which prevents the loss of blood becomes soft and disintegrated under the influence of suppuration, the degenerative process being *entirely due to septic causes. In* the second variety the plug becomes displaced while it is still healthy though friable, either in consequence of some derangement of the hæmostatic appliance *or else owing to injudicious movements* on the part of the patient or of his attendants. If gunshot wounds could only be kept aseptic from the first the latter *form of secondary* hæmorrhage would alone be met with. It is, however, very difficult to ensure the surgical cleanliness of gunshot wounds. First-aid is for the most part administered by stretcher-bearers whose hands are always *more or less soiled.* "Never," exclaims Surgeon-Major Moingeard, "shall we succeed in convincing these men of the capital importance of asepsis to an extent sufficient to induce them to wash their hands before touching open wounds." On active service it is, unfortunately, not always possible to apply surgical science in its perfection. Even at dressing stations, although the *personnel* be efficient and the *matériel sufficient, the* surgeon must content himself with "verifying the security of the provisional hæmostatic measures already adopted, making them, if possible, still more *secure. Only* very exceptionally shall he venture to apply ligatures in cases where he finds it is impossible to affix appliances. Needless to say he must not dream of arresting an internal hæmorrhage. He should at once apply an antiseptic and occlusive dressing without adventuring on any exploration whatever. We will say more—he should carefully refrain from all explorations of the wound." Not until the ambulance is reached can a wounded soldier hope to receive to its full extent the surgical aid which he would have in a civil hospital. The greater portion of Surgeon-Major Moingeard's paper is devoted to the mode of applying hæmostasis, according to the region of the body implicated. In the section on Wounds of the Neck the following interesting story is quoted *from* Larrey's *Clinique Chirurgicale*:—

> During the siege of Acre, while he was superintending a battery of artillery, M. Arrighy, who afterwards was Duke of Padua, received a bullet in his neck which severed the external carotid artery close to its separation from the internal and just before its entrance under the parotid gland. The fall of the wounded nobleman and the jets of blood spurting from both ends of the divided vessel attracted the attention of the gunners, *and one of* them, a highly intelligent man named Pélissier, had the presence of mind to promptly insert his fingers into these orifices, thus arresting the hæmorrhage. Having been immediately summoned I ran to the wounded personage's aid amidst balls and bullets. A compressive bandage, preceded by firm graduated compresses methodically applied, to my great astonishment, arrested the rapid march of death and saved this officer, who was cousin-german to the general-in-chief, Bonaparte.

Surgeon-Major Moingeard concludes his article with short chapters on Venous Hæmorrhage, Secondary Hæmorrhage, and General Treatment. In his summing-up he emphasises the need of *better instruction* for stretcher-bearers.

The Public Medical Services.

It seems to be forgotten by the War Minister and all concerned how much turns upon the question of supply and demand in the matter of obtaining eligible candidates for the medical services. Great changes have, speaking generally, taken place in regard to the medical profession of late years. The medical curriculum has been increased from four to five years, entailing increased expense, longer courses of study, and a diminished number of students at the medical *schools than was formerly the case.* The public medical services have not kept pace with this altered state of things, while the *amount of foreign service, of responsibility*, and of work have gone on increasing. But even apart from these things there are underlying social questions and considerations which tend to affect the popularity of the services, and medical officers are tired, after having undergone all the hardships of a campaign in which they are conscious of *having done their best, of being subjected to adverse criticism* on the part of so many irresponsible or incompetent judges. Shortly put, the foregoing may be taken as expressing a very general feeling.

The Boer Prisoners at Ahmednagar.

As our readers are aware there was a great outcry raised when it was known that a large batch of *Boer prisoners* were to be quartered at Ahmednagar. It was pointed out in vain that an Indian station which was considered good enough and healthy enough for the occupation of British soldiers might suffice for the Boers. Ahmednagar is really a healthy elevated station and a pleasant and popular place of residence, and we now learn that the Boer prisoners are well satisfied with it and "full of gratitude at the kindness and consideration with which they have been received." They are housed in roomy, airy huts, enjoy a good deal of liberty, and are supplied with good rations and suitable clothing, and are, in short, very well off. The water-supply is, it is believed, of excellent quality.

Army Medical School, Netley.

The eighty-second session of the Army Medical School will be brought to a termination on Saturday, June 29th, when the prizes will be distributed by the Right Hon. the Earl of Northbrook, G.C.S.I.

On Wednesday, *June 19th, Colonel W. J. Charlton* and the officers of the Royal Army Medical Corps quartered at Netley entertained Surgeon-General J. Jameson, C.B., the retiring Director-General of the Army Medical Service, at a farewell dinner.

Surgeon-General A. F. Preston, A.M.S., has been selected for a distinguished service pension of £100 per annum.

Correspondence.

"Audi alteram partem."

"SURGICAL OR MEDICAL TREATMENT IN GASTRIC ULCER?"

To the Editors of The Lancet.

Sirs,—Dr. L. Wheeler's letter in The Lancet of June 15th is a valuable contribution to gastric surgery, but he gathers from my paper in The Lancet of June 8th that I recommend "that, broadly *speaking,* all *cases of gastric ulcer should be* operated on as soon as the diagnosis is assured." I am afraid the length of my paper has so wearied the attention of the reader as to lead to its not being understood. I am certainly not in favour of operating on all cases of gastric ulcer, and I am as certainly not in favour of waiting till the *diagnosis* is assured before operating. Nothing is more fatal to success in abdominal surgery than waiting till the diagnosis is assured. And, paradoxical as it may seem, no surgeons perform so large a proportion of futile exploratory laparotomies as those who work with physicians who wait until the diagnosis is "assured" (and too often assured wrongly). *The right and simple rule is that every other reasonable, available, and safe means of diagnosis, which does not involve delay, should be exhausted before an operation is decided* *upon.* If such a study of the case leaves one in absolute perplexity, that very condition of doubt may be the strongest reason for operating.

With regard to the case which Dr. Wheeler reports himself, mprovement appears to have begun immediately after he pened and washed out the stomach with boric solution, nd not before, in spite of morphia and rectal feeding. It vould be interesting to have the history of this case after eaving hospital. It is of the kind which often comes to either gastro-enterostomy or pyloroplasty or Loreta's operation fter all. With regard to the patient whom Dr. Wheeler *did ot* operate on, a case of gastric ulcer which was treated on imilar lines was discharged seven weeks ago from the West London Hospital apparently quite well. She returned in hree days. Thanks to the acumen and decision of Dr. Otto Grünbaum, then house physician, I was asked to perform aparotomy, although the diagnosis was far from assured (at east, according to ordinary rules)—e g., there was absolutely o abdominal tenderness. But perforation of a gastric ulcer ad taken place. As there were pus and lymph in the pelvis s well as over the stomach and the perforation was 24 hours ld the patient had a narrow escape.

Apropos of my inquiry as to the present condition of Dr. Wheeler's Case 1, I may mention that seven years ago man nearly died from gastric hæmorrhage at Brighton. fterwards his stomach dilated and his pyloric obstruction ot worse so gradually that for years until the very day efore his death (the 23rd ult.) he went to no medical man. n attack of tetany occurred and Dr. Gilbert Richardson as then called in. He promptly saw that nothing but urgery could save the patient, even if it were not too late or that. The tetany was relieved, but death occurred from xhaustion ten minutes before the surgeon's arrival.

I am, Sirs, yours faithfully,

Grosvenor-street, W., June 15th, 1901. C. B. KEETLEY.

"PRELIMINARY MEDICAL EDUCATION."

To the Editors of THE LANCET.

SIRS,—Dr. Lombe Atthill, in the explanation he has hought fit to offer in your columns of his reasons for voting gainst the resolution which I proposed at the General Medical Council, says that he voted against the resolution ecause it withdrew from the Council the main questions nvolved by the recent action of the London Colleges—viz., heir ignoring the resolutions of the Council requiring five ears' study at a recognised medical school and their onsequently ceasing to require a certificate of registration from the candidates for their licence, and he states urther that I announced that the vote on my resolution ould be final, so that not alone was no expression f opinion possible on these points but no alternative ourse other than complete submission by the Council to the ecision of the Colleges was possible under the resolution. s regards this last allegation Dr. Atthill is entirely in rror on a question of fact, of course unintentionally. If he ill refer to your report of the discussion he will find the ollowing: "The President asked Dr. McVail whether he ntended, if his motion were carried, to represent the matter o the Privy Council. Dr. McVail replied that if the motion ere carried, as he hoped it would be, he would be perfectly ontent to leave the matter there until next session. The Royal Colleges and the other bodies would then have an pportunity of understanding the position of the Council in he matter."

I also said that my motion would not tie the hands of any ther member of Council who might choose to propose any ther resolution on the subject. It was, therefore, entirely pen to Dr. Atthill or to any other member of the Council o have moved an amendment to my resolution or, had the esolution been carried, to have followed it by another irecting whatever action the proposer might have thought o be desirable. It is, therefore, not the case that my esolution was in any sense final or withdrew any aspect of he question from the consideration of the Council. The esolution was as follows:—

> [illegible] hysicians of [illegible] n so far as [illegible] subjects of [illegible] that these [illegible]

This directly relates to the first of the main questions lluded to by Dr. Atthill—viz., the resolution of the Council equiring five years' study at a recognised medical school, and yet he gives as his reason for voting against the resolution that it did not relate to the five years of curriculum. My resolution distinctly included the question of the substitution by the Royal Colleges of secondary and other schools as places in which the first year of professional study might be taken instead of at a recognised medical school as desired by the Medical Council. But as Dr. Atthill is of opinion "that when possible physics and chemistry should be taught as subjects of preliminary education" it would have been impossible for him to have done otherwise than vote against my resolution, but it is difficult to understand that his reason for doing so was because I did not propose stronger action against the Colleges for conduct of which in this particular he strongly approves.

The terms of my resolution were carefully framed so as to vindicate the position of the Council as to the courses of study for the first professional examination and yet to leave it open to the Council to postpone ulterior action for six months to enable the English Colleges to reconsider their action. I did not include in the motion any reference to registration in the Students' Register, as under the Medical Acts the Council cannot enforce such registration. The institution of the Students' Register was essentially a voluntary arrangement on the part of the universities and incorporations. It was extremely convenient and saved much trouble both to the students and to the officials of the licensing bodies, but any one of these bodies might ignore the Register should it so decide. My resolution dealt with the sufficiency of the courses of study, and the supervision of medical education is the primary function of the Medical Council. The Council is the General Council of Medical Education and Registration. Clause 20 of the Medical Act of 1858 is as follows:—

> In case it appears to the General Council that the course of study and examination to be gone through in order to obtain any such qualification from any such College or body are not such as to secure *the possession by persons obtaining* such qualification of the requisite knowledge and skill for the efficient practice of their profession, it shall be lawful for such General Council to represent the same to His Majesty's most Honourable Privy Council.

The very circumstance that *study* is in this clause undefined, imposes on the Council the duty of informing *itself regarding every particular of the medical curriculum of* every one of the licensing bodies as to the nature and extent of the curriculum which each of them should as a minimum require from candidates for its degree or diploma. The Council is left entire liberty as to the manner in which it will arrive at and express its opinion as to the courses of study which should be required. Just as in the matter of infamous conduct in a professional respect there is no definition in the acts and as courts of law have held that the decisions of the Council as to what constitutes infamous conduct are final and not to be reviewed by any judicial body in the kingdom, so does the twentieth clause in the Act give an equal power in the matter of the medical curriculum, and all powers and privileges possessed by any licensing body in virtue of charters or *deeds* of incorporation are subject to the twentieth clause of the Medical Act. It is the imperative duty of the Council to lay down its minimum of the course of study in any subject that it may deem requisite, and if the opinion of the Council be persistently ignored by any medical authority the Council must then perform its final duty of reporting to the Privy Council. This step the Council can never be eager to take, and no member of the Council is less desirous than I am to adopt such a course, and therefore it was that my motion was so framed as to leave the door still open to the Royal Colleges to conform to the Council's opinions. The Medical Council, however, having by a small majority refused the *motion I proposed*, and having then proceeded to other business, has left the English Royal Colleges free to continue in their present course of conduct, and the first year of the medical curriculum can continue to be taken by candidates for their diplomas at any one of a large number of ordinary schools, and that in courses which as to their length are altogether undefined, and this year at school is to be the first of the five years of their medical curriculum. No doubt other licensing bodies may be tempted to act likewise and, further, may regard themselves as being quite safe from any action on the part of the Council in making other departures in subsequent parts of the curriculum from what the Medical Council has declared to be necessary. Chaos indeed may result, and the work of 40 years be wholly undone. But I hope that at a very early date the Medical

Council may take steps to define rigidly and unmistakeably its position as to medical study under the unlimited duty and power which devolve on it under the twentieth clause of the Act of 1858.—I am, Sirs, yours faithfully,

Glasgow, June 19th, 1901. D. C. MCVAIL.

"THE SWALLOWING OF FOREIGN BODIES."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 15th I notice a short article on "The Swallowing of Foreign Bodies" which concludes with the moral that "when a patient swallows his false teeth he knows it and does not infer it from symptoms." The following case will show that even this moral is not always a safe one to act upon. A woman of powerful physique and not hysterical sent for me one afternoon because she had just swallowed her false teeth. It was an incomplete gold set that had been given her many years back, when she was in domestic service, by her mistress, and in consequence of her having lost several teeth since the plate was made it fitted very loosely in her mouth. She told me that she was eating some cabbage soup and that she felt an unusually large piece of cabbage catch in one of the sharp angles of the plate and that the cabbage and the teeth slipped down her throat at the same time. On examining her abdomen and pressing firmly over the lower border of the stomach she complained of a sharp cutting pain which she, of course, concluded was the gold plate. I suggested making a thorough search over the house before attempting an operation, but the woman was indignant that I could suppose her capable of making such a mistake, and declared that she had positively "felt the teeth going down." I therefore promised to call the next morning and to do what was necessary for the recovery of her lost property. In the meantime, however, she had found her teeth among some potato parings and so no surgical interference was needed. I concluded that the teeth had actually slipped out of her mouth during the day without her noticing it and that she must have swallowed a bone with the soup, which passed through her intestines without giving rise to any symptoms. I have always been very suspicious of "false teeth" episodes, but particularly so ever since I saw a gastrotomy done for a set that was afterwards found in the patient's trousers pocket.

I am, Sirs, yours faithfully,
ERNEST O. B. VOISIN, M.R.C.S. Eng.
St. Heliers, Jersey, June 15th, 1901.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—Dr. Andrew Wilson states of me that "in one case he appears a Weismannian out-and-out; in another he figures as an opponent of the view that it is the germ plasm alone that can transmit features from one generation to another." Dr. Wilson is mistaken in both instances. I have never been a supporter of Weismann and I have always maintained the obvious truth that it is the germ plasm alone that can transmit features from one generation to another—obvious since from the germ alone spring future individuals. As Dr. Wilson thinks it interesting perhaps I had better explain. Years ago Mr. Galton propounded the view that acquired characters are *not* transmissible. The higher plants and animals are compounded of cells, each one of which in a very real sense is a separate living entity. All the cells are differentiated for the performance of different functions, reproduction being reserved for the germ cells. Now there is no more reason for supposing that muscle or liver or any other of the somatic cells are concerned in reproduction than for supposing that germ cells are concerned in the production of motion or of bile. In other words, there is no reason for supposing that each one, or indeed any one, of all the millions of traits acquired by every man (for example) so impresses the germ cells that the *particular* trait the parent acquired is reproduced by the child. *A priori* the thing appears incredible. *A posteriori* the plant and animal kingdoms have been ransacked and no single instance of the transmission of an acquirement has ever been proved. We are entitled, therefore, to believe that acquired characters are not transmitted. Weismann supposes that some of the germ plasm of the parent is separated off and handed on practically unchanged to the offspring. He adds amazing complications in the shape of ids, idants, biophors, and so forth, the bearers of heredity. If his hypothesis be true it must follow as a corollary—*but as a mere corollary*—that acquired traits are not transmissible. But a theory that only inborn characters are transmissible is one thing: a theory as to *how* inborn characters (to the exclusion of acquired characters) are transmitted is quite another thing. The former (Mr. Galton's) theory rests on the solid ground of well-ascertained fact—on the cell theory. The other (Weismann's theory) is absolutely unsupported by evidence. It may or may not be true. There is not a shred of evidence one way or the other. No one has seen, or at least no one can recognise, the germ plasm, much less an id or an idant. Medical men commonly assume that the neo-Darwinian (Mr. Galton's) theory stands or falls by Weismann's metaphysical speculations. It would be as reasonable to decline to admit the fact of a man's death unless it were first proved that he died in a certain specified way.

While it is unbelievable that the characters acquired by alcoholic parents are transmissible to offspring, the assumption that parental ill-health due to alcoholism, or to alcohol circulating in the parent's blood and acting directly on the germs, may injure the latter and through them the offspring is a much less incredible assumption. But here, again, the evidence points to an opposite conclusion. Germinal changes are known to be transmissible to remote descendants. Did alcoholism injure the germs, a race that used it would, by the accumulation of injury during generations, tend towards extinction. I am not aware that the South Europeans, for instance, who have used alcohol for thousands of years, are approaching extinction or even that they are more degenerate than Terra del Fuegians who, Dr. Sharp notwithstanding, have never used alcohol. I know only that they have become extremely temperate, apparently through the elimination of the more drunken.

"M.D., B.S." complains that "the discussion of this question seems to have degenerated into a vain and unprofitable attempt to get at the meaning of Dr. Archdall Reid's theories." I daresay he is right, but the fault is not mine. I have endeavoured to avoid the mention of my theories. They did not seem to me relevant to the point at issue—the point as to whether temperance legislation is productive of *immediate* good or harm. I challenged opponents to mention a single instance when, under the *ordinary* conditions of civilised life, repressive legislation had not been productive of increased drunkenness as well as of many attendant evils—a very definite challenge to which there has been no reply. However, if "M.D., B.S." desires to have any definite point cleared up he has only to state it and I will do my best. Meanwhile, it is a pity that he did not verify his references. I suppose with care it would be possible to misrepresent the report of the Research Committee of the Society for the Study and Cure of Inebriety more completely than he has done, but it would be very difficult. He had no justification in the summary published in THE LANCET.

I have only one remark to add, to which, however, I wish to give all the emphasis possible. When the question of temperance reform is raised in such an organ as THE LANCET the interest it excites is not limited to a few medical men. The present controversy has been watched by the officials of every important temperance organisation in the kingdom. It is their business to keep themselves informed of the effects of temperance legislation all the world over, and presumably they are eager in the cause of "reform." The readers of THE LANCET will appreciate at its proper value the fact that though temperance reform has been tried on an enormous scale, these gentlemen have not attempted to controvert my very grave assertion that it has invariably been productive of increased debauchery when tried under conditions less than half as onerous as those which prevail in England at the present day.—I am, Sirs, yours faithfully,

Southsea, June 11th, 1901. G. ARCHDALL REID.

A CASE OF HERMAPHRODITISM.

To the Editors of THE LANCET.

SIRS,—I was asked to prescribe for a girl, aged 20 years, who had never menstruated. As, however, I did not care to do this without previous examination I obtained the necessary consent. I then found that the vagina ended in a cul-de-sac, and in making this examination the knuckle of my index finger came against a swelling in one labium. I then exposed and found two fully-developed testes, one in each labium majus, and each in a sac of its own. They were freebly moveable and there was testicular sensation. The clitoris was an inch long. The genital hair did not extend on to the abdomen but was limited to the pubes. The mammæ were small and poorly developed, although larger than in the male. The patient was tall and slight, with a coarse voice, and suffered now and again from hysteria and "ovarian tenderness," for which she had been blistered. There was sexual orgasm. It may be also mentioned that her brother has a hare-lip.

I am, Sirs, yours faithfully,
J. THOMSON SHIRLAW, M.B. Edin.
Upholland, near Wigan, June 13th, 1901.

"LOCAL v. GENERAL ANÆSTHESIA IN CERTAIN CASES OF ABDOMINAL SURGERY."

To the Editors of THE LANCET.

SIRS,—It would almost appear that the skilled anæsthetist can only look at anything involving the administration of anæsthetics from his own high level. In my letter on the above subject published in THE LANCET of June 8th I endeavoured, amongst other things, to point out that the administration of a general anæsthetic in a critical case, whilst, perhaps, fairly safe in the hands of a very competent anæsthetist, became a source of shock and danger in the hands of an unskilled administrator thereof. Will Dr. J. Blumfeld deny this? In operations of urgency in the country we can seldom obtain the services of a skilled anæsthetist, and Mr. T. H. Morse was, I consider, when speaking of his own extensive experience in such cases, justified in asserting that "shock varies in proportion to the skill of the administrator and is often dependent upon the duration of the operation and hence upon the amount of the anæsthetic which is inhaled."

I am, Sirs, yours faithfully,
Norwich, June 16th, 1901. S. JOHNSON TAYLOR

THE BALLYMAGRAN SCANDAL AND THE IRISH LOCAL GOVERNMENT BOARD.

To the Editors of THE LANCET.

SIRS,—For the information and satisfaction of my friends who are readers of THE LANCET permit me to acquaint them that the Local Government Board have at my request held their sworn inquiry into the circumstances of the sad death of Mrs. Jones, and their decision is "that he [the medical officer] was not guilty of any neglect of duty in connexion with this case."

I am, Sirs, yours faithfully,
R. D. PATTERSON,
Medical Officer, Caledon and Ballymagran Dispensary District
Caledon, June 18th, 1901.

CORPORATION MEDICAL APPOINTMENTS IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—At the desire of the Honourable the Colonial Secretary, Cape Town, I inclose copy of a letter dated 11, Selborne-road, Denmark-hill, S.E., 23rd April, 1901, addressed to a medical gentleman residing in Cardiff, and signed by "Fred. E. Willson," regarding vacancies for corporation medical officers in South Africa. I am to state that the Cape Government knows nothing whatever of Mr. Fred. E. Willson or of the appointments to which he refers, and I would feel obliged if you would be good enough to publish this letter and its inclosure in order to warn medical men against putting any faith in Mr. Willson's representations.

I am, Sirs, yours faithfully,
D. TENNANT, Agent-General.
100, Victoria-street, London, S.W.,
June 11th, 1901

[COPY]

11, Selb[illegible]

DEAR SIR,—Your fav [illegible]
the appointments are [illegible]
salary of £2 per day [illegible]
20 men are wanted *immediately*. There is a grand opportunity for fully-qualified men under 40, genera' [illegible]
ability, sound common sense, and no [illegible]
for outfit, passage money, and initial [illegible]
No need to purchase a practice. I [illegible]
information and advise at personal I [illegible]
above qualifications By appointm[illegible]
venience April 25th, 26th, and 27th, May 1st and 2nd.

Yours, &c.,
(Sgd.) FRED. E. WILLSON.

"DENTISTRY AND THE SERVICES."

To the Editors of THE LANCET.

SIRS,—I am glad to see that the scheme for the appointment of army dental surgeons which was recently published in THE LANCET as the result of my experiences in the Imperial Yeomanry Hospital at Deelfontein, South Africa, has so far borne fruit that four dental surgeons have been appointed and have sailed for the Cape. On their arrival the question will arise as to how their services can best be employed. Four dental surgeons are of no appreciable use to meet the requirements of the army, and as they are not to be supplied with workroom appliances they will not be able to deal with the worst cases that have to be invalided home for lack of artificial teeth. I think the best way would be to send all four of them to any one of the military hospitals, where the record of their work would indicate the necessity of sending 40 more to follow them as quickly as possible. The soldiers' teeth have been neglected, and on an average there is a day's work for a dental surgeon in the mouth of every one of them. This statement is confirmed by statistics derived from other sources. The appointment of four dental surgeons to each of the general hospitals would go far towards meeting the urgent needs of the army in South Africa, and the authorities could obtain a good deal of help from the practitioners in large towns to deal with cases which would otherwise have to be invalided home for artificial teeth. In Cape Town and Kimberley I found dental friends and practitioners who, I am sure, would do their best to meet the authorities in supplying dentures for special cases. I need scarcely refer to the proposal of Mr. Morton Smale, who thinks that the Royal Army Medical Corps should undertake the treatment of the soldier's teeth. A large number of additional army surgeons would be necessary, and it is not clear that they would prove better dentists or less expensive than ordinary dental surgeons.

I am, Sirs, yours faithfully,
June 17th, 1901. F NEWLAND PEDLEY.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—It is arranged to hold a dinner on Wednesday, July 24th, in the Whitehall Rooms of the Hôtel Métropole at 7 P.M., at which the Harben Medal will be presented to Professor Koch in recognition of his great scientific services. A large number of influential guests have already accepted invitations to be present, including Lord Lister, Lord Strathcona, Professor Brouardel, &c. The council will be glad to welcome anyone desirous of being present. Tickets for the dinner are one guinea (inclusive of wine) to be obtained from myself, an early application for which is desired.—I am, Sirs, yours faithfully,

W. A. BOND, M.D. Cantab.,
Honorary Secretary.
19, Bloomsbury square, W.C., June 18th, 1901.

LIME-WATER FOR OUR STREETS.

To the Editors of THE LANCET.

SIRS,—During the last few years I have on several occasions advised the employment of freshly-made lime-water for watering our streets with in hot weather. The reasons which in the first instance led me to make the suggestion were the following: (1) the observation that animal excreta set mortar into a hard substance like egg-shell; (2) that lime tends to petrify and preserve wood under favourable conditions, as is seen in old half-timbered houses; (3) that it binds together bits of dry dung and so prevents them flying about in the wind; (4) that its slight solubility enables it to act gradually and for a lengthened period, as all perfect antiseptics should act; and (5) that it renders the surface of wood less greasy and slippery.

During a recent visit to Vienna I have had the good fortune to see lime employed in the simplest possible manner for the disinfection of sewage at a new institution for the open-air treatment of phthisis. This institution, which is situated in an ideal spot in the hills of the Wiener Wald, is in every way excellent and up-to-date, and no pains seem to have been spared with regard to sanitary arrangements. Though I have always been a believer in the value of lime as a disinfectant I must confess to a little surprise when I discovered how simply and effectively it could be applied to the treatment of sewage. A day's sewage is collected in one of three tanks and with it is mixed "fresh milk of lime" in the proportion of 1 to 2 per cent. The whole is then allowed to settle for 48 hours. The clear fluid is drained off and the sediment is used for manure and is said to be of great value. I was assured that the purifying action of the lime was so complete that the treated fluid when allowed to escape from the tank was purer than the water of neighbouring mountain streams. I need not remind surgeons that fresh lime, if strong and in quantity, is a powerful caustic, but in weak solution it forms a soothing antiseptic dressing for the most sensitive conditions of the skin, such as scalds, burns or weeping eczema. Our streets have not been very offensive during the recent spell of hot weather because they have been constantly dry. If now in their cracked condition they become wet every crevice will be converted into an offensive little cesspool, unless the streets are watered with a suitable antiseptic. After what I have stated I do not think it is too much to ask that the proper authorities should give lime a fair—by that I mean a scientifically conducted—trial.

I am, Sirs, yours faithfully,
ALFRED EDDOWES, M.D. Edin.

Wimpole street, W., June 17th, 1901.

ACTIONS FOR NEGLIGENCE.

(FROM A LEGAL CORRESPONDENT.)

ALTHOUGH actions for negligence against members of the medical profession are of comparatively rare occurrence, their importance is such that a short outline of the law upon the subject may be found useful. No statute throws any light upon the question. The Medical Acts make no reference to the liability of members of the profession for malpractice, and the attitude of courts of justice can only be discovered from a consideration of the cases which have arisen from time to time.

The question, "What is negligent conduct on the part of a physician or surgeon?" is one of fact rather than law, just as the duty of the medical man towards his patient should be defined rather by reference to rules of etiquette and the working of his own conscience than by a strict legal formulary. It is the lot of the practitioner to be at the beck and call of his patients at all hours of the 24; it is his lot to have to continue in attendance upon a case when the chance of remuneration is small and where that remuneration, even if paid to the full, must constitute but a poor return for the fatigue of long journeys and the anxiety of many weary hours. In such circumstances it is satisfactory to know that slight carelessness or neglect will not necessarily be visited with a fixed punishment, but that all the facts will be considered before liability is attached to the unfortunate practitioner.

An attempt is sometimes made to draw a hard-and-fast distinction between qualified and unqualified practitioners when liability for negligence is under discussion. As a matter of fact no clear distinction can be drawn, the question being entirely one of degree. Nevertheless, the ignorance of a man who undertakes to perform a difficult operation is a matter which may have an important bearing upon his liability for negligence, and in so far as the quack is more ignorant than the registered medical practitioner he may be said to be under a greater degree of liability. A review of the cases in which damages have been recovered for negligent surgical or medical treatment generally discloses the fact that the heaviest penalties have been awarded against defendants who were unqualified. In Ruddock *v.* Lowe (4 F. & F. 519) the defendant, who kept an anatomical museum in the Strand, was unqualified, but he kept a qualified assistant as the ostensible practitioner and professed himself a master in the art of healing certain disorders "which he never undertook unless he could guarantee a perfect cure." The plaintiff who was suffering from such a disorder desired the advice of the defendant, who saw him frequently, treated him ignorantly and improperly, and administered an improper medicine, by which he was rendered worse instead of better. The jury found a verdict for the plaintiff, damages £200.

The question whether the practitioner has been guilty of negligence is one of common sense and of fact for a jury to decide upon. Chief Justice Tindal thus summed up to the jury in the case of Lamphier *v.* Phipos (8 C. & P. 475): "Every person who enters into a learned profession undertakes to bring to the exercise of it a reasonable degree of care and skill. He does not undertake, if he is a surgeon, that he will perform a cure, nor does he undertake to use the highest possible degree of skill. There may be persons who have higher education and greater advantages than he has, but he undertakes to bring a fair, reasonable, and competent degree of skill, and the question is whether the injury must be referred to the want of a proper degree of skill and care in the defendant or not." It was also pointed out by Chief Justice Erle in Rich *v.* Pierpont (3 F. & F. 35) that "it is not enough to make the defendant liable that some medical men of far greater experience or ability might have used a greater degree of skill, nor that even he might possibly have used some greater degree of care."

In America the correct rule has been said to be that a physician and surgeon when employed in his professional capacity is required to exercise that degree of knowledge, skill, and care which physicians and surgeons practising in similar localities ordinarily possess (see Dunbauld *v.* Thomas, Am. Law Dig., 1900, p. 3656).

As has been said, the question of what is negligence is one which depends on the facts of each particular case. The following American cases are useful instances. Thus in Edwards *v.* Lamb (Am. Law Dig., 1900, p. 3656), where the plaintiff under the direction of the defendant assisted in dressing a wound of her husband and became infected with poison by reason of slight scratches on her fingers, the defendant, who knew of the danger, was found to be guilty of negligence in assuring her there was none, since he was not justified in assuming that her hands were free from such wounds. In another extraordinary case it was decided that a physician is under no obligation while a person is his patient to tell her or her husband that a fragment of a needle broken in a surgical operation was left in her body, but it is his duty to tell her so when discharging her as his patient from his care (Eislein *v.* Palmer, Am. Law Dig., 1899, p. 1870).

The question, "To whom is the practitioner liable?" is often one of considerable importance as he is frequently employed by the relatives of his patient, while the injury attributable to negligent treatment is sustained by the patient alone. It has often been decided that although the practitioner may have been employed by the next friend of his patient yet the patient can bring an action and recover damages for negligence. Thus in Gladwell *v.* Steggall (5 B. N. C. 733) the plaintiff by her next friend sued the defendant, "who was a clergyman and who practised also as a medical man," for damages for a misfeasance. It was held that the fact of the plaintiff submitting to the defendant's treatment was sufficient proof of an allegation of employment of the defendant by her.

This leads to the consideration of the question whether surgeons and others who hold staff appointments and who give their services gratuitously to the patients in hospitals can be sued for negligence. The writer is not aware of any action having been successfully brought against a hospital surgeon for negligence, the distinctive feature of his position being that what he does he does gratuitously. The few cases which are upon record, although they come very near to the point, fall short of actually deciding it. The consequences of holding surgeons irresponsible in such cases were thus pointed out by Baron Garrow in the case of Pippin *v.* Sheppard (11 Price, 400): "In the practice of surgery the public are exposed to great risks, from the number of ignorant persons professing a knowledge of the art, without the least pretensions to the most necessary qualifications, and they often inflict very serious injury on those who are so unfortunate as to fall into their hands. In cases of the most brutal inattention and neglect the patients would be precluded, frequently, from seeking damages by course of law, if it were necessary to enable them to recover that there should have been a previous retainer on their part of the person professing to be able to cure them. In all cases of surgeons retained by any of the public establishments it would happen that the patient would be without redress, for it could hardly be expected that the governors of an infirmary should bring an action against the surgeon employed by them to attend the child of poor parents who may have suffered from his negligence and inattention."

While the liability of a hospital surgeon for his personal acts has been left unsettled, it has been decided that a hospital surgeon is not liable for the acts or defaults of nurses in the hospital to whom the more minute care of the patients is entrusted. Thus in the case of Perionowsky *v.* Freeman (4 F. & F. 977) the plaintiff, who had been a patient at a London hospital, sued two of the surgeons for maltreatment there by causing him to be placed in a bath so hot that he was scalded and injured. It was proved that the bath had been ordered by the defendants but that it had been actually administered by the nurses. Chief Justice Cockburn, in leaving the case to the jury, said. "The defendants cannot be held liable for the negligence of the nurses unless they were near enough to be aware of it and to prevent it. No doubt persons who go as patients into hospitals are not to be treated with negligence, but, on the other hand, medical gentlemen who give their services gratuitously are not to be made liable for negligence for which they are not personally responsible." A verdict was returned for the defendants. So much is generally left to the nurses and attendants at a hospital that the above case will serve to relieve the staff of much responsibility.

Passing on to consider a few cases of more recent date it is interesting to notice that save in cases of exceptional hardship juries seem to be inclined to decide actions for professional negligence in favour of the practitioner. In a case which occurred in March, 1899,[1] the plaintiff sought to recover damages from the defendant in respect of alleged negligence in his professional treatment of her. It appeared that he had opened an abscess and inserted a drainage-tube. This tube was afterwards missed, but it was supposed that the patient had lost it when she removed the bandages. The wound eventually healed, but ultimately a second operation was performed by another practitioner, and a piece of indiarubber tubing was removed from the arm. The defendant denied that he had been guilty of any negligence. Corroborative evidence was given by two other practitioners who said that it would not have been justifiable to slit up the sinus in order to search for the tube. The jury found a verdict for the defendant whose case had been conducted by the Medical Defence Union.

Where the damages arise through some mistake against which no practitioner can at all times be on his guard it is in the highest degree important that the defendant should be absolved from responsibility. In Russell *v.* Crec[2] the plaintiff, a clerk, sought to recover the sum of £24 damages in the Clerkenwell County-court for the alleged negligence of the defendant, a medical practitioner, in certifying that "he was suffering from scarlet fever and was therefore unable to follow his profession." It turned out that he was in reality suffering from "erythema." It was shown that the case was extremely doubtful and that the spots visible were very deceptive. Judge Meadows White said that he could not see where the negligence came in and the action was dismissed.

The question must sometimes occur to the practitioner whether he is in duty bound to go on with a case after he has seen the patient once. Continued attention may in some cases prove very irksome, especially if the patient lives at a distance and is not a regular patient. The following Scotch case[3] serves to show that while a medical man is not bound to continue attendance in an emergency case a jury may sometimes be persuaded to give damages. It appeared that the defender as the nearest medical man had been called in to attend a labourer who had sustained a fracture of the tibia of his right leg just above the ankle. Upon examination the defender found that the man was not in a fit state to have the leg set and for several reasons he advised that he would be better at the Edinburgh Infirmary, six miles off. Having done up the pursuer's leg so as to guard it against the dangers of removal he sent him to hospital, intimating at the same time that he would have nothing more to do with the case. He was not the regular attendant of the pursuer nor was he the surgeon for the mill at which the pursuer had been working. Further, the defender never entered the pursuer's name in his books nor did he ask any fee for what he had done. After seeing the pursuer the defender was himself laid up with influenza for a month, when he again saw the pursuer, who had never been moved to the hospital. By that time the mischief had been done, and as the result of an operation which was then found necessary one leg was shorter than the other. Lord Adam, who charged the jury in an action brought against the defender for negligence, said that the case turned altogether on the question whether the defender undertook in November to give his continuous professional attendance to the pursuer. He also remarked: "Because a doctor attends a man in an emergency it does not follow that he is bound to go on with the case. Unless it is proved that besides doing what he did he also undertook to treat the pursuer as his patient the obligation ceased." In spite of this very explicit direction the jury returned a verdict for the pursuer with £50 damages. Although the jury decided in favour of the plaintiff the direction of the learned judge in the above case represents an accurate statement of the law, and it corresponds with the attitude taken up by American lawyers. In Keller *v.* Lewis (65 Ark. 578) a physician gave his services gratuitously to a patient who knew he was going away. It was held that he was responsible only for such treatment as he had administered personally and that he could not be held liable for any negligence or want of skill on the part of a physician who was subsequently called in.

Apart from the risk of having an action lodged against him for negligence the practitioner may also find his alleged negligence set up in answer to a claim for fees. It was long ago decided that if the defendant in such an action receives no benefit, *in consequence of the plaintiff's want of skill,* the latter cannot recover (Kannen *v.* McMullen, Peake, 59); but the remuneration of a practitioner who has used due skill and diligence does not depend on his effecting a cure. In the case of a surgeon, if an operation which might have been useful has failed in the event he is nevertheless entitled to charge; but if it could have been useful in no event he has no claim (per Alderson, J., in Hill *v.* Featherstonhaugh, 7 Bing. 574).

From a report of the case of Matcham *v.* Lacey,[4] it appears that at least one member of the county court bench takes the view that when a medical man undertakes a case he must go through with it to a finish, although the parents or other persons who have immediate control of the patient persistently refuse to take the medical man's advice. In the case under notice the plaintiff retired from a case on this ground and sued for his fees up to date. The learned judge found in favour of the defendants, remarking that a medical man is bound to continue in attendance upon a case which he takes up and that if he leaves it at an early date he must forego his entire fee. It is very doubtful whether this is a correct statement of the law. If the medical attendant gives sufficient notice to his patient and entrusts the case to a brother practitioner in whom he has confidence it would be hard indeed to find him guilty of negligence and so to deprive him of any reward, especially when his motive for leaving the bedside was his clear perception that those in charge persistently refused to take his advice or, although able to afford the fees, the patient's friends were determined not to pay. A solicitor will often refuse to proceed without a payment on account. A medical practitioner, although his doing so would not be consistent with the highest professional etiquette, should be allowed to take the same course in emergency.

CENTRAL LONDON THROAT AND EAR HOSPITAL, GRAY'S INN ROAD.—The annual meeting of the committee and subscribers of this hospital, of which H.R.H. the Duke of Connaught is the patron, was held last week, Captain Hutton presiding. The report read by the secretary, Mr. F. Kershaw, showed that the ordinary income of the hospital for the past year amounted to £2032 and the expenditure to £2328. The liabilities at the present time were no less than £3579, of which £2000 were owing to the bankers; an urgent appeal was made for funds to redeem these debts and also for the erection of an operation room, towards which the council of the Prince of Wales's Hospital Fund had given a donation of £150.

THE CONTAMINATION OF POST-OFFICES.

ACTION TAKEN BY THE FRENCH GOVERNMENT.

(FROM OUR SPECIAL CORRESPONDENT.)

THE candidates for employment under Government are far more numerous than the vacancies that occur. This is not only the case with regard to the better paid posts of the Civil Service, but even the poorest positions in small post-offices, for instance, are eagerly sought after. But if the demand for employment under Government is keen in England it is even more accentuated in France. Such a form of occupation is thoroughly in keeping with the natural instincts of a large section of the French people. There the spirit of commercial enterprise is not so widely developed, but there is a very strong love of officialdom, consequently it is more easy for the French Government than for the English Government to obtain the civil servants needed by the various State Administrations. Under such circumstances there is no absolute need to improve the conditions of employment. Even if these are unhealthy and the civil servants die off rapidly it will be easy to replace them. This is a callous view to take, but then Governments or Ministers are so busy and have so many matters to manage. The poorer and less influential classes are thus especially likely to be neglected. It is therefore particularly to the credit of the present French Government that it should have gone out of its way to improve the condition of its humblest servants. As an employer it is especially in the postal and telegraphic services that the State engages the service of a large number of persons at a low rate of pay. Now in France, and more particularly in Paris, it has been found that an exceptionally large proportion of the post-office clerks and others employed indoors died from tuberculosis. This disease is not so prevalent among the letter-carriers whose work keeps them out of doors. Consequently, in the month of April, 1900, a circular was sent by the Government to the chiefs of all the post-offices insisting that an official notice should be hung up warning the public not to expectorate on the floor. But the first injunctions sent out produced very little effect, and Dr. Mignot, member of the Government Commission of Tuberculosis, was instructed to draw up a special report on the subject for the administration of the posts and telegraphs. Dr. Mignot's report bears the date of Jan. 9th, 1901, and has become, as it were, the scientific sanction of the more energetic measures now taken by the Government.

Dr. Mignot points out that the Commission appointed by the President of the Council—i e., M. Waldeck-Rousseau—to discover the most practical means of checking the spread of tuberculosis had lengthily discussed the dangers arising in localities where a large number of persons gather together. In such places one single individual suffering from tuberculosis and expectorating on the floor might, they considered, endanger the health of hundreds of other persons. On the other hand, as the means by which tuberculosis is spread are now known, this danger might be almost entirely dispelled if the proper precautions were taken. Where many were employed, and especially if they were employed by the State, it was easy to take these precautions. A useful example could thus be given. Dr. Mignot regrets he cannot produce precise statistics because those suffering from the earlier stages of tuberculosis were not known to the Administration. Nevertheless, it was ascertained that in 1899 there were about 71,000 persons employed in the French postal and telegraphic services. Of this number 200 were certified to have died from tuberculosis during that year and 88 had to be dismissed because they were suffering from this disease. This is equal to a mortality of 28·1 per 10,000 and a loss to the service of 40 5 per 10,000 through tuberculosis alone. But if we take into consideration those who die after they have been removed from active service the mortality from tuberculosis among this category of civil servants is likely to be about 40 per 10,000. The general mortality from all diseases was 1557 during the years 1897, 1898, and 1899, and the deaths from tuberculosis amounted to 561, not including those who had been dismissed from the service; therefore, out of 100 deaths about 36 are due to tuberculosis. Taking the entire population of France the deaths from tuberculosis are set down at 54 per 10,000, but this higher figure deals only with the towns where there is a regularly established statistical service, and this does not exist in many rural districts for the general public, though it does for the persons in the employ of the State. Also, the higher figure includes persons of all ages and conditions of health, while those engaged in the postal service have to pass a medical examination before they are admitted. The fact that the employés in the postal services are especially exposed to tuberculosis is more emphatically demonstrated if only the statistics of Paris be taken. In 1899 the post-office clerks, &c., numbered 1500. Of these, 43 died from tuberculosis and 50 had to retire from the service in consequence of this disease. This made a loss equal to 62 per 10,000, whereas the mortality from tuberculosis for the entire population of Paris amounted to only 49 per 10,000.

The first precaution to be taken, according to Dr. Mignot's report, is to prevent the contamination of the post-offices by providing numerous spittoons. These should not be put on the floor but on stands about three feet high, and they should contain an antiseptic solution. The whole question resides in preventing the desiccation of the sputa and its conversion into dust that can be conveyed to the lungs with the breath. Till such measures have been enforced Dr. Mignot insists that every post-office must be considered as a contaminated place. The method of cleaning the offices must be altered. Sweeping and dusting only propagate the evil. The broom, says Dr. Mignot, "is a terrible engine of death." The floors must be wiped over every day with wet rags and scoured once a week. This practice has already been introduced in barracks and police-stations. The ideal would be to wash in the same manner the walls and the ceiling. The floor, especially where the public is admitted, should be made of an impermeable substance. But the greater part of the offices have been built in a most unsuitable manner and there are any amount of dark corners, angles, and recesses where dangerous dust accumulates. The telephone cabinets are also dark and unsuitable recesses. All this, it is urged, must be altered when new offices are built. With regard to the postal servants themselves, no candidate suffering from tuberculosis should be accepted. Instruction should be given to all as to the best means of protecting themselves from this disease. Finally, when anyone contracts tuberculosis he should be sent away and properly treated. The medical examination before admission to the service should be more strict; the written details given of the diagnosis of illness during service should be more detailed, especially when the complaint is contagious. When a case of tuberculosis does occur it is rarely possible to nurse the patient properly in his own house, and yet the State cannot abandon its servants. Therefore, and in spite of the considerable cost involved, Dr. Mignot recommended that a sanatorium should be built for the employés who suffer from tuberculosis.

Following upon this advice a sanatorium for tuberculous patients has now been established near Paris, and M. Millerand, Minister of Commerce, Posts, and Telegraphs, sent out a strongly-worded circular to the chiefs of all the post-offices, which was dated Feb. 1st, 1901. In the first sentence M. Millerand complains that in spite of numerous recommendations issued in regard to the sanitary measures to be adopted at the post-offices these offices are still left in a very defective condition, and he adds: "I absolutely insist that this state of affairs, which is so prejudicial to the health of the employés and of the public, shall cease." Therefore M. Millerand gives instructions that on the receipt of this circular spittoons containing a 2 per cent. solution of sulphate of copper must be placed in the post-offices. They should be of a cone-like shape and of enamelled ironware. The contents must be thrown down the drains at least every other day, and the posters instructing the public as to the importance of utilising the spittoons are to be put up in prominent positions in the post-offices. Any postal servant who does not observe the rules must be reported. Further, the circular adds that the floors of all the post-offices are to be rendered impermeable by the application of a coal-tar mixture. Then when the leases of the premises occupied are terminated they must not be renewed unless the proprietor consents to effect sundry sanitary improvements, including the substitution of tiles for the wooden floors. Nor must the sweeping with brooms be allowed—cloths wet with a 2 per cent. solution of carbolic acid must be used instead. Wall-papers are to be replaced whenever possible by oil-paint, coloured varnish, or other substances that can be easily washed. Nor must posters and public announcements be allowed to remain too long on the walls, but must be renewed when dirty or dusty. All the chairs, desks, and other furniture must be kept scrupulously clean. The telephone cabins must be washed out every day with a carbolic acid solution. "Further," adds M. Millerand, "I attach the greatest importance to the frequent cleansing of the urinals and water-closets and that the offices should be amply ventilated, especially during the hours when the staff is absent" Other equally practical instructions are given and this in an authoritative and positive manner. Then the circular concludes with the warning that inspectors will be sent round to see if these instructions have been carried out.

In regard to the construction of new post-offices a Ministerial decree was issued on Jan 30th, 1901, stating *that all plans for such edifices must be submitted to the* medical committee attached to the Ministry before they can be sanctioned. Further, all premises which are to be used for the postal services must be inspected by medical officers especially appointed for that purpose. Details for the application of this decree are given in a Ministerial circular, dated April 1st, 1901. This circular first explains that, so far, the tendency has been to instal the postal services in buildings that already exist and that were not constructed for this special purpose and consequently are so defective as seriously to compromise the health of the employés. Therefore, the circular urges that whenever possible instead of renting existing premises buildings should be erected especially for the postal services. The local postal authorities are urged to endeavour to come to some mutual agreement with private banks and other financial establishments which need offices possessing somewhat similar sanitary advantages To facilitate such endeavours the architects attached to the administration, acting according to the indications given by the Ministerial Medical Committee, have drawn up plans of model post offices, and these accompany the circular. In regard to the premises occupied for the postal services there is also a circular forbidding the employment of lead in the paint used. No building contract is to be signed unless those concerned undertake to employ oxide of zinc instead of lead in the paint used for the walls, doors, &c. From all this it will be seen that the Minister of the posts and telegraphs has exercised paternal watchfulness over the 71,000 persons who are under his control. The great difficulty is the ignorance and indifference of the postal employés themselves Their knowledge of bacteriology and of sanitary science is very limited and all the rules and restrictions which M. Millerand is endeavouring to impose are apt to be qualified as grandmotherly legislation that is vexatiously meddlesome and trivial. But there is no better form of education than that derived from object-lessons, and as these sanitary measures are more widely enforced the persons concerned will gradually realise their advantage and lend themselves to their more strict and effective application.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

An Important Scheme in Connexion with the Indian Census —The Biological Treatment of Sewage in Bombay City.—The Decline of the Plague Epidemic —Precautions at Simla —The Indian Medical Service.—Some Acquired Habits of the Natives of India —The Continued Famine

A SCHEME has now been sanctioned whereby various investigations are to be undertaken in connexion with the census operations with regard to ethnography, or the systematic description of the history, structure, traditions, and religious and social customs of races and castes in India, and also their anthropometry. Each local government will appoint a superintendent who will have a staff under him and who will have funds to reward persons to draw up the monographs on the various castes for the provinces of Madras, Bombay, Bengal, the North-West Provinces, the Punjab, Burmah, the Central Provinces, and Assam. The total cost will exceed £10,000

Probably on account of the successful institution of the biological treatment of sewage at the Leper Asylum, Bombay, the commissioners of the city are about to adapt this system to a part of the drainage of the city. It is proposed to construct a septic tank to contain one day's flow, or 300,000 gallons, of sewage. The process is much more rapid in the higher temperature of India than in England, so that this construction gives a liberal allowance. The tank is to be made into compartments in case it requires to be cleaned. In addition to the septic tank there will be bacteria beds to carry on the aerobic purification These will be filled automatically and will thus give to the beds their periods of aeration. The gas which comes off from the septic tank is to be collected and utilised for the illumination of the works at night. The effluent, which in the Leper Asylum has been proved to be so remunerative on the farm, will in the city drainage scheme unfortunately be allowed to run into the sea. This system of treatment of sewage is also to be applied to several adjacent villages and will in this installation be utilised for the irrigation of a farm. It is expected that the annual cost of the latter experiment will be more than *covered by the yield of the farm. As the farm has been* made to pay at the Leper Asylum I do not see why it should not, if properly managed, be made to pay elsewhere. The adoption of this scheme by the Bombay municipality speaks well for the work already executed by the engineer at the Leper Asylum

The epidemic of plague is declining rapidly. The total deaths throughout India for the week ending May 25th were 1427, as compared with 1918 in the previous seven days. The deaths, however, are still in excess of the corresponding period of last year The mortality has dropped in Bombay city from 295 to 199, and in the Presidency from 457 to 97. In Bengal the worst places are Calcutta (47 deaths), Patna district (38 deaths), Saran district (78 deaths), Gaya district (36 deaths), and Darbhanga district (57 deaths). There has been a slight rise in the Jumna district of Kashmir. An unfortunate occurrence is reported from Patiala territory. Inoculation had been introduced for a few cases of plague, and amongst others a Hindu lad was inoculated but died within an hour. The medical man declared the death to be due to plague, but the villagers were up in arms and put the death down to inoculation This incident has of course acted adversely to the progress of inoculation and it shows apparently great carelessness If the lad died from plague he must have been ill when he was inoculated. Some authorities seem to think that this operation can be left to almost anybody to perform, but it would seem that these public performances of inoculation by officials should be only made under direct European supervision. A somewhat similar death following inoculation occurred some time ago in Calcutta and it is said to have acted to the discredit of inoculation ever since

The proximity of plague cases to Simla has determined special precautionary measures being taken to prevent plague cases occurring in that place. A plague hospital and camp have been constructed and the usual arrangements for segregation have been made. During the last fortnight a large quantity of plague prophylactic serum has been sent out from the Plague Research Laboratory, Parel, Bombay, *some going to Shanghai, some* to the Seychelles, and some to South Australia.

There is a proposal to increase the strength of the Indian Medical Service, as recent experience has shown it to be seriously undermanned. Until this has been decided upon the further proposal to divide the furlough reserve of the service between the military and civil departments will stand in abeyance.

So called German "whisky" has apparently attracted the taste of the poorer classes in India. It has had a largely increased sale during the past year, probably from its cheap price of about Rs 3 a gallon. British spirit costs over Rs. 8 and French spirit nearly Rs 10 a gallon Recent revelations are said to have shown that this "whisky" sent to India is made of methylated spirits, coloured, sweetened, and flavoured. It has been known for some time that well to-do natives have developed a taste for whisky and other strong alcoholic beverages, and that this altered taste is extending rapidly. Whether these forms of alcoholic liquors will be withstood by the native constitution remains to *be seen. Another* change of habit is said to have occurred in the more general use of umbrellas by all classes of natives A serviceable umbrella is largely imported which sells at about a rupee. The importance of this innovation consists in the probable effect of the sun's rays after the prolonged use of the umbrella has caused the native's head to become more sensitive. Some authorities will assert that sunstroke only occurs in those who are overfed or who have alcohol in their stomachs. It is at any rate very uncommon among those who are in repose—exercise being a powerful factor in its determination. The native with his dark eyes and black skin can readily withstand the glare of the sunshine. This it is which causes the chief distress and minor ailments to the pale-faced European. Even among the latter sunstroke is probably not so common as is generally supposed. In the course of a few years, however, we may hear of the natives getting sunstroke.

The numbers under famine relief continue to increase. Half a million people appeal for assistance. In Bombay province the totals are 353,247; Bombay native States, 41,462; Baroda, 25,649; Hyderabad, 13,913; Central India States, 4712; and Madras, 5165. Fortunately there is every hope of a satisfactory monsoon.

May 31st.

MANCHESTER.

(From our own Correspondent.)

Heaton Park.

As was anticipated a fortnight ago the Manchester City Council are repeating the performance which they indulged in over Trafford Park. On June 5th, at the monthly meeting of the council, the report of the Parks and Cemeteries Committee, which was adverse to the purchase of the park, was received for entry on the minutes and an amendment in favour of offering £210,000 was rejected by 44 to 28. The effect of this is that the resolution of the council passed in April last authorising the Parks Committee to consider the question of purchase still holds good, but that further negotiations, if any, are to come from the other side. It is pretty generally agreed that a mistake was made in letting Trafford Park slip and regret is felt, not only that an open space valuable from a hygienic standpoint was lost to the city, but that a good bargain for the ratepayers was thrown away. If Heaton Park could be kept as an open space without purchase it would be all very well, but that cannot be. The alternative to purchase is that before very long it will be utilised by the jerry-builder and covered by inferior houses, so that the smoke by which, according to some of the councillors, it is already affected will be considerably increased. It is time for the smoke nuisance in Manchester and Salford to be more vigorously dealt with, and with the increased use of gas and electricity there ought not to be much difficulty in freeing the city from much of the cloud that now overhangs it.

The Ancoats Explosions.

The sewer explosions in Ancoats on May 3rd were referred to by the deputy chairman of the Rivers Committee at the meeting of the Manchester City Council on June 5th. He said that they occurred on the introduction of a lighted candle into the bell mouth of a sewer, and that "a certain firm of manufacturers" had admitted that the emission of "a certain inflammable effluent" from their works into the sewer had caused the explosion. This effluent should have gone into a catchpit but got into the sewer "by accident." This "certain firm," the name of which was not revealed, had undertaken to pay for the damage done. Dr. Bishop said that he had been connected for seven years with a society which had been agitating against the pouring of noxious fluids into the sewers, and that it was humiliating to the council that it had taken no action in the matter until an explosion had occurred. In a letter to the papers the Rev. S. Nugent Perry, rector of St. Mark's, says that "for many years the people have been bitterly complaining to the corporation authorities of the foul smells and, in my opinion, dangerous gases which have forced their way into their dwellings from the sewers." It seems that the manholes have been fitted with iron plates which kept the gases from escaping into the open streets but transferred them into the houses where the nuisance was increased tenfold. In a report of the Sanitary Committee dated December, 1898, some of the sewers were ventilated into the chimney of some works, but "with regard to the Canal-street sewer it has not been thought advisable, owing to the highly-explosive nature of the liquids used, these being a source of great danger should a small quantity even get accidentally into the sewer." So that this danger has not been sprung suddenly on the city authorities. Mr. Perry also says that where the manholes were sealed up, "notwithstanding protests, there have been three explosions—viz., Oct. 3rd, 1898, when the manholes were blown open and the pavement disturbed in Sandal-street; on Whit-Sunday, 1900, in the dwelling-house, 267, Bradford-road, where the cellar-flags were blown up; and the recent one on May 3rd." Mr. Perry thinks that the explanation of the deputy chairman is poor consolation to those who are compelled to live in the neighbourhood. With this opinion most of us will agree. It is perhaps a difficult and delicate question as to whether the city authorities or "a certain firm of manufacturers" should be held as the more culpable. The one knows of a danger and applies a remedy which is not a remedy but merely diverts explosive forces from one place to another, while the firm of manufacturers allow their catchpit, about which we are told very little, to fail in its duty and explosions take place. There seems to be a failure of duty and of obligation on both sides. But corporations are said to have no souls, and the same proverb may possibly be applicable to "firms."

No Accommodation for Lunatics.

A case was brought forward at the meeting of the Chorlton Board of Guardians on June 7th which illustrates some of the difficulties that occur in dealing with lunatic patients. The workhouse master reported that he had refused admission to a man brought by the police, as they had at the present time no accommodation. "The man was insane, of suicidal tendencies, and dangerous to others." It was stated that the receiving room in the male lunatic ward was full and even overcrowded and that there were two padded rooms continually occupied. There were also three suicidal inmates and four delirium tremens patients under treatment. The chairman said that the Manchester Board of Guardians were not troubled with lunatics apprehended by the police. They were taken in charge, and as early as convenient they were taken to the police-court and certified by a medical man that they were lunatics and should be removed. The magistrates on the bench signed the order and the police took the patients to the asylum. The superintendent of an asylum must take the case in. He thought the Chorlton Board were entitled to the same treatment as other boards. With the asylums and the workhouses full, the provision of additional accommodation ought to be pushed on with more energy than seems at present to be expended on the matter.

Overcrowding of the Chorlton Union Workhouse.

At a recent meeting of the Chorlton Board of Guardians Mr. Jenner-Fust, an inspector of the Local Government Board, made some strong remarks on the overcrowded state of the workhouse. He said that no one could go through the wards without seeing that day-rooms were occupied as dormitories, beds put close together, and all the usual signs of the accommodation being insufficient. It was decided to provide additional accommodation in December, 1897, but for various reasons the extensions had not been carried out. One reason probably was the doubt as to the future of the imbeciles and epileptics, but legislation with respect to them had apparently been indefinitely postponed, so that it was all the more necessary for the guardians themselves to deal with the question of accommodation for the indoor poor. He recommended the plan of building two new pavilions so as to allow of future extension, to be occupied at first by the imbecile and epileptic patients, which would relieve the serious overcrowding of the main building, and of a new nurses' home. When the new asylum was built the pavilions would afford accommodation for the sick. It seems that there are still 90 children in the workhouse, and Mr. Jenner-Fust said that the guardians should direct their attention to the removal of the whole of them. He thought that they could hire premises which with slight alteration would enable them to accommodate the "ins and outs" who could not be transferred to Styal, and he also expressed the hope that the Joint Asylum Committee would "come to some definite decision in proceeding with the scheme for dealing with imbeciles and epileptics." As regards the extension of the Styal homes Dr. J. M. Rhodes referred to the delay of the Local Government Board in passing the plans. He did not know who was to blame but he wished the ratepayers to understand that the guardians were not in fault.

Manchester and Salford and a Small-pox Hospital.

At the meeting of the Salford Council on June 5th it was carried by the casting vote of the mayor that the Health Committee should reopen negotiations with the Manchester

Corporation in favour of the joint use of the proposed hospital for small-pox to be built in Drinkwater Park Objection was made that Manchester patients would have to be taken through the streets of Salford at the risk of spreading sickness in the borough, but Dr. C H Tattersall had assured the proposer of the motion that there would not be the least danger No scheme can be brought forward to which objection will not be raised, but if this one can be carried out it must prove an economy to both towns which should be pleasing to the ratepayers It is curious to notice how the long suffering ratepayers are always brought forward in opposition to every effort made for the improvement of the health and surroundings of a community, and how many deeds of narrow short sightedness and unwisdom are done ostensibly for their benefit

Stockport Water supply.

The supply of water to Stockport has for a long time been somewhat anxiously considered The corporation may therefore be congratulated on the preamble of the Bill to enable them to go to the Hayfield district for an additional supply, at an estimated cost of £800,000, having been proved

June 18th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS)

Sanitation at Weston super-Mare

IN many country districts and in small towns the sanitary officials are not encouraged by the local authorities under whom they serve to hunt up insanitary conditions, it is *usually deemed sufficient for them to deal with such as are* brought to their notice, but it is not often they receive definite instructions to neglect a duty cast upon them by an Order of the Local Government Board It might be supposed, too, that a seaside resort would be the last place in which such neglect would be recognised, but the urban district council of Weston super Mare at their meeting on June 13th instructed the inspector of nuisances not to inspect and report upon the drainage or condition of empty or other houses unless a *bonâ-fide* nuisance exists or is alleged to exist, the council considering that it is no part of the duty of the sanitary authority to undertake work of a private nature which more properly belongs to the business of a sanitary engineer. It is generally held that systematic and regular inspection of all premises is the best mode not only of discovering nuisances but of preventing slight nuisances becoming grave dangers The Weston super-Mare District Council apparently think otherwise and need to be reminded of the Order of the Local Government Board dated March 23rd, 1891, Article 19 (3) of which, referring to the duties of an inspector of nuisances, requires that "he shall by inspection of the district both systematically at certain periods and at intervals as occasion may require keep himself informed in respect of the nuisances existing therein that require abatement" The members of the district council might also read with advantage Section 92 of the Public Health Act, 1875, which states that "it shall be the duty of every local authority to cause to be made from time to time inspection of their district with a view to ascertain what nuisances exist calling for abatement under the powers of this Act'

Electric Light at Pontypridd Workhouse

The board of guardians of the Pontypridd Union have decided to light the workhouse at Pontypridd with electric light The installation will consist of about 500 incandescent lamps generated from plant to be erected on the premises

Overcrowding.

Although the census returns have shown the estimates of the population in several colliery districts in Glamorgan to have been placed too high there is undoubtedly in many localities a great deal of overcrowding of houses A very flagrant instance is reported from Margam, where in a three-roomed house with two bedrooms there were living in addition to the father and mother and six children as many as five adult lodgers

Admission of Visitors to Workhouses

There has been some discussion recently at the meetings of the Tavistock (Devon) Board of Guardians in reference to the guardians allowing members of the Salvation Army to visit the sick wards of the workhouses, the medical officer holding that as he was responsible for the health of the inmates the right of allowing these visitors entrance should be vested in him The Local Government Board were eventually appealed to on the matter, and at the meeting of the guardians held on June 14th a letter was read from that authority stating that the guardians could allow members of the Salvation Army or of any other religious denomination to visit the sick at the workhouse, but if the medical officer considered that the holding of services in, or the admission of visitors to, the workhouse would be detrimental to the health of the inmates his views should be attended to

Isolation Hospital for Tiverton and District

Tiverton (Devon) Isolation Hospital was formally opened on June 8th The hospital is built on the block system and contains accommodation for 13 beds; the grounds have an extent of three acres The cost of the building, including the land, has been £6300, and the maintenance is estimated at about £700 per annum

June 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS)

Glasgow University

THE celebration of the four hundred and fiftieth anniversary of the foundation of Glasgow University has proved in every respect an unqualified success The programme of events was certainly a somewhat crowded one, but the energy and *organising ability of the University authorities proved fully* equal to the occasion, and the lighter social festivities as well as the more severe academic exercises were carried through with a smoothness and completeness on which all concerned are to be heartily congratulated Perhaps the most striking feature of an occasion which must necessarily remain a conspicuous landmark in the history of the University was the number and distinction of the delegates sent to convey congratulatory and sympathetic messages from sister universities and learned bodies in all parts of the world The only academic event which in this respect can afford a parallel, at least in recent years, is the celebration of Lord Kelvin's jubilee as a professor some seven years ago In addition to men of distinguished reputation sent from all parts of Great Britain and from India and the colonies representatives were present from the principal universities of the continent and the United States, two native Japanese professors presented a congratulatory address from the University of Tokyo, and a sympathetic message was announced from the Pope To all these Glasgow extended a hospitable welcome and as an expression of her appreciation many of the foreign visitors were honoured by receiving the honorary LL D degree The ceremony at which the delegates were presented followed the commemoration service in the Cathedral and was a very impressive occasion It was introduced by an eloquent address delivered by Principal Story who read a message of congratulation received from His Majesty the King The most prominent event of the second day's proceedings was the graduation ceremony, at which an address on James Watt was delivered by Lord Kelvin and one on Adam Smith by Professor Smart Among those who received the honorary degree of LL D were most of the foreign delegates and a considerable number of representatives from the United Kingdom Among the best-known names were those of Lord Balfour of Burleigh, the Marquis of Dufferin, Lord Strathcona, Lord Reay, Lord Glasgow, Lord Beauchamp, Major General Sir Ian Hamilton, Lieutenant-General Sir Archibald Hunter, Sir William Selby Church, Sir William MacCormac, Sir James Reid, Sir Henry Roscoe, Professor Bayley Balfour, Professor Chiene Professor Fraser (all three of Edinburgh), Professor Cunningham (Dublin), Professor Oliver Lodge (Birmingham), Principal John Yule Mackay (Dundee), Professor Ogston (Aberdeen), Principal Sir George Philipson (Durham), and Sir John Williams (University College, London) Mr Carnegie received the same degree, and his advance to the platform not unnaturally was greeted with a special ovation For the first time in its history the University included ladies among its honorary graduates, and the Principal, in the name of the Senate, "capped" Mrs. James Campbell, Mrs. John Elder, Miss Emily Davies, and Miss Agnes Weston. The third day of the ceremonies included an oration on William Hunter by Professor John Young who traced Hunter's connexion with the University and delivered an eloquent appreciation of his work and of the services which he rendered to his *alma mater*, more especially in the gift of the museum which bears his name. The last academic event of the jubilee celebrations which remains to be chronicled was the opening of the new Botanical Institute which has been designed and equipped on a most elaborate scale. The ceremonies in connexion with this attracted much interest. Sir Joseph Hooker formally declared the institute open and in doing so gave an account of the life and work of his father who was Professor of Botany in the University of Glasgow for a period of 20 years. The vote of thanks to Sir Joseph Hooker was proposed by Lord Lister. Speeches were also delivered by Sir William Thistleton Dyer and by Professor Bayley Balfour. The social features of the celebrations were both numerous and varied. They included conversaziones, garden parties, a banquet, a students' ball, and a gaudeamus, and all of these were marked by great vivacity and success. The corporation entered heartily into the University scheme and gave a banquet in honour of the University and its official guests, and the University, not to be outdone in courtesy, made the Lord Provost an honorary LL.D. Apart from the sentimental value and interest of all these proceedings they may be expected to attract attention to the wants of the University and to its attempt to raise a large sum for extending its laboratory and research equipment. Some evidence of this is found in the fact that during the week the Principal has received one cheque for £5000 and a second one for £2000. Mr. Carnegie's munificent benefaction will do much for the universities and for Scotland, but it will not satisfy every need. Instead of checking the generosity of others it is hoped rather that it will provide the proverbial force of a good example.

Presentation of a Statue of Queen Victoria.

At a meeting of the Town Council of Paisley on April 24th 1900, ex-Provost Clerk stated that a gentleman who wished his name to be withheld had offered to present the town with a statue of Queen Victoria. The council unanimously accepted the offer and the central site of the William Dunn-square was granted for its erection. Much speculation took place as to the identity of the donor, but it became known only quite lately that he was Dr. John Baird Hunter of Paisley. On June 11th the statue was unveiled by Miss Hunter, a sister of the donor, in the presence of a large and enthusiastic assembly. Dr. Hunter then delivered an address, after which Provost Wilson spoke in eulogistic terms of the public spirit which actuated many present and former inhabitants of Paisley and concluded by formally accepting the gift in the name of the citizens. A meeting was afterwards held in the town hall, at which Dr. Hunter presided and various speeches were made. The statue is of bronze on a square granite pedestal, the height of the pedestal being 7 feet and that of the statue 6 feet 10 inches. It represents Her Majesty as at the date of the Diamond Jubilee. The inscription on the front is, "Victoria Dei Gratia Regina Imperatrix Praestantissima, 1837–1901."

Public Baths, Aberdeen.

The city architect has been ordered to report as to the cost of putting into order for the busy season the swimming pond and some of the private baths at the foot of Constitution-street in the premises of the Aberdeen Swimming Bath Company, lately acquired chiefly for the Corporation Tramways Department.

Proposed Public Sanatorium for Aberdeen.

At the last meeting of the Aberdeen United Trades Council the following motion was unanimously adopted: "Considering the fact that nearly one-fifth of all the deaths in this city are caused by tubercular disease, and that professional opinion is unanimous in declaring that when taken in its early stages it is curable, this council agrees to approach the town council with the view of asking them to consider the advisability of erecting in the country a hospital for the open-air curative treatment of consumption." The chairman estimated the cost of 10 acres of land at £1000, and of providing buildings for 160 patients annually at £6000, and the yearly charge at £3400, equal to about 1¼*d.* per pound additional on the rates. It was also resolved that a request should be made that a deputation should be heard by the Corporation's Public Health Committee.

University of Aberdeen.

Mr. Pittendreigh Macgillivray, A.R.S.A., Edinburgh, who has been commissioned to execute the proposed mural medallion portrait of the late Principal Sir W. D. Geddes for King's College, is to visit Aberdeen and to recommend a suitable position.—Aberdeen University sports were held on June 12th and resulted in a popular and successful gathering.

Small-pox at Peterhead.

A mild case of small-pox is being treated in hospital and no danger of the disease spreading is entertained.

Unhealthy Area in Aberdeen.

The old Bursars' Hotel and other buildings, Nos. 59 to 62, Exchequer row, included under the Provisional Order for dealing with the unhealthy area in that quarter, are to be removed.

Another new Public Park for Aberdeen.

Aberdeen's city chamberlain has been instructed by the town council's Parks Committee to negotiate with the Northern Lighthouse Commissioners, owners of Girdleness Lighthouse, as to the marking out of the boundary line of a new public park, near the bay of Nigg, for the use of the people of the municipal ward of Torry, on the south side of the River Dee. The new park is to be under the charge of the superintendent of Duthie Park and part of the ground will be at once ploughed up and sown with grass seed.

June 18th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The National Association for the Prevention of Tuberculosis.

AT a meeting of the executive committee of the National Association for the Prevention of Tuberculosis held on June 5th at the Royal College of Physicians of Ireland a resolution was adopted unanimously in favour of bringing before the notice of the Commissioners of National Education the advisability of appointing lecturers to give instruction on the prevention of consumption to the students in the various training colleges for teachers in Dublin. Sir Charles Cameron's report as to the working of the voluntary system of notification adopted by the Dublin Corporation stated that since October last 65 cases of phthisis had been notified, chiefly by the dispensary medical officers, but that in the majority of cases the patients' friends refused to allow the infected rooms to be dealt with. In all cases application for liberty to disinfect was made, but in only about one-fourth was it acceded to. The proper remedy, Sir Charles Cameron said, was the conferring upon the health authorities of compulsory powers of disinfection and the inclusion of tuberculosis in the list of diseases which must be notified, but until that power was obtained the public health departments of the city and the two outlying townships of Pembroke and Rathmines were prepared to carry out the work of disinfection free of cost. The Marquis of Dufferin and Ava presided at the last meeting of the Belfast branch of the society and made some interesting observations. The mortality, he said, from consumption in Ulster, which otherwise was as healthy a region as any in the United Kingdom, was double that of Lancashire and quadruple that of the healthiest counties of Great Britain.

Irish Medical Association.

The sixty-second annual meeting of this association was held in the Prince's Restaurant, Belfast, on June 11th. The incoming President, Professor Whitla, in his address, after thanking the members for electing him and welcoming them to Belfast, referred to the objects and aims of the association. He dwelt upon the grievances of the Irish dispensary medical officers—superannuation, abuse of the ticket system, locum-tenents, and annual holidays—which the association had tried to remedy, as well as upon such points as the rights of factory and police surgeons, consultants' fees, sanitary prosecutions, lunacy fees, &c. He regretted that of 800 Poor-law medical officers less than one-half were members of the association and that of the 2500 medical men residing in Ireland only about one-fourth were enrolled. The annual report showed that the council had held five meetings and the committee of council 38 meetings during the year. 44 members had been elected. £158 had been expended in law costs during the year, the greater part being incurred in the effort to secure the rights of medical officers to four weeks' vacation. On the motion of Mr. S. B. Coates (Belfast), seconded by Mr. J. W. Olpherts (Downpatrick), the report and statement of accounts were adopted. Sir Charles Cameron moved, and Dr. A. H. Benson (Dublin) seconded, the following motion which was passed :—

> That the council be instructed to take such proceedings as may seem advisable in support of the Poor-law Officers' Superannuation Bill now before Parliament.

On the motion of Mr. T. Myles (President of the Royal College of Surgeons in Ireland), seconded by Dr. J. B. Story (Dublin), it was agreed :—

> That as the duties of Poor-law medical officers require ceaseless attention at all hours, day and night, it is in the interest of the sick poor as well as of the medical officers that a period of needful rest be provided, and that the Council be instructed to continue their exertions to have Article 28 of the Dispensary Regulations so amended as to secure to medical officers their reasonable demand for an annual vacation:

Dr. L. Kidd (Enniskillen) moved, Dr. S. Agnew (Lurgan) seconded, and it was passed :—

> That the Council be requested to consider the advisability of revising the articles of association generally, and especially with regard to the formation of branches and making the association a defensive one.

On the motion of Mr. O'C. J. Delahoyde (Dublin), seconded by Mr. J. Taylor (Tandragee), it was carried—

> That this meeting declares that the salaries at present paid to the dispensary and workhouse medical officers are inadequate and totally disproportionate to the labour involved in the onerous and important duties they have to discharge, and therefore that the council be instructed to take this question into immediate consideration with a view of formulating a scheme whereby a minimum salary, rising by periodical increments to a certain maximum, shall be fixed for all Poor-law medical appointments, and that copies of this resolution be sent to the different licensing bodies and their coöperation requested to attain its object.

A vote of thanks to the retiring President (Sir P. C. Smyly) and to the press concluded the meeting, after which the visitors were shown over the great shipbuilding yard of Harland and Wolff. Subsequently they attended the garden party given by the Lord Mayor and Lady Mayoress to welcome home the Ulster Yeomen. In the evening the annual dinner was held in the Prince's Restaurant, when Professor Whitla, the President, occupied the chair. In addition to a large number of members the following guests were present: The Lord Mayor, the High Sheriff, Sir James Henderson, D.L., Sir R. J. McConnell, Bart., D.L. Sir Charles Cameron, Professor Byers (President of the North of Ireland Branch of the British Medical Association), Professor W. H. Thompson (President of the Ulster Medical Society), Lieutenant-Colonel Thomsett, P.M.O., R.A.M.C., Mr. C. J. Clibborn (Local Government Board inspector), Mr. H. G. Croly (Dublin), Mr. T. Myles, Mr. R. Agnew (Local Government Board inspector), Mr. J. R. Fisher (editor of the *Northern Whig*), and Mr. A. McMonagle (editor of the *Ulster Echo*). After a very well-served dinner the following toasts were given. "The King" and "The Queen, the Duke and Duchess of Cornwall, and other members of the Royal Family," were proposed by the President. "The Lord Mayor and Corporation of the City of Belfast" was proposed by the Chairman, to which Sir Daniel Dixon, D.L. (the Lord Mayor), replied. Sir James Henderson, D.L., gave "The Navy and Army," to which Lieutenant-Colonel Thomsett replied. Professor J. A. Lindsay proposed "The Medical Corporations," to which Mr. Myles responded. The toast of "The Irish Medical Association," coupled with the health of the President, was given by Professor Byers (President of the North of Ireland Branch of the British Medical Association), to which Professor Whitla replied. Sir Charles Cameron proposed "The Press," which was acknowledged by Mr. McMonagle and Mr. Langford Symes (editor of the Journal of the Association). Dr. McLaughlin proposed "The Health of the Local Government Board," to which Mr. C. J. Clibborn replied. "The Health of the Dinner Committee" was proposed by the chairman, and Dr. J. J. Robb, Mr. Coates, Dr. J. Nelson, Dr. H. L. McKisack, and Dr. J. Colville responded. During the evening selections were rendered by a band and vocal items were given by Mr. D. Glasgow and Mr. W. Livingstone. Prior to the commencement of the business meeting those present were hospitably entertained to light refreshments by the new President (Professor Whitla).

Sanitary Condition of Portadown.

Mr. C. J. Clibborn, Local Government Board inspector, in his report in reference to his recent inspection of Portadown, urges the necessity on the part of the urban council that they should no longer delay to take steps to adopt a more perfect system of sewerage. Stone-built sewers should be replaced by pipe sewers so as to prevent the soakage into the surrounding soil of deleterious matter. A consultant engineer should advise as to the best possible scheme to adopt to have the sewage purified before its discharge into the rivers or as to the adoption of some system of septic tanks for the final disposal of sewage. A supply of good drinking-water is urgently required. The condition of insanitary premises should be remedied and houses which are unfit for human habitation should be dealt with, and on this subject the medical officer of health should be asked to give a detailed report. The house drains connecting with the main sewers should be fitted with modern disconnecting traps and the back yards should be better paved so as to prevent soakage of deleterious matter into the surrounding soil. The Portadown Urban Council is to consider carefully this important report which is so condemnatory of the sanitary state of that thriving town.

The Irish Poor-law System.

At a meeting of the Armagh County Council on June 13th, the following motion, proposed by Dr. E. Magennis, J.P., was unanimously passed :—

> That in the opinion of the County Council of Armagh the time has now come when the Government should appoint a Commission to inquire into the working of the Poor-law system in Ireland with a view to introduce some other method of dealing with the poor, or to make such changes in the present system as will lessen the very heavy expenditure imposed on the ratepayers and be more in accordance with the wishes of the people.

The evils of the present system, which everyone must admit, were fully pointed out by Dr. Magennis.

The Midwife Question at Caledon.

In THE LANCET of June 1st, p. 1574, appeared a reference to a sworn inquiry by the Local Government Board of Ireland in regard to an extraordinary verdict of a local jury condemning Mr. R D. Patterson, the medical officer of the Caledon and Ballymagran district, for "neglect of duty" in the case of a woman who died from puerperal septicæmia. The result of this sworn inquiry, brought about by a public meeting held in Caledon to protest against the verdict and demanding an investigation of the circumstances, is "that he [the medical officer] was not guilty of any neglect of duty in connexion with this case." The life of a dispensary medical officer in Ireland is truly an unenviable one, but fortunately, as in this case, there is occasionally a fair public opinion, and in every circumstance the Local Government Board still exists as a just tribunal to which in all cases there is the right of appeal. Mr. R. D. Patterson is entitled to the full sympathy and congratulation of his private and professional friends on his triumph in this case.

The Belfast Hospital for Sick Children.

Dr. W. C. Steen having resigned the post of assistant physician to the Belfast Hospital for Sick Children, Dr. R. M. Beatty has been appointed in his place.

Cork South Charitable Infirmary: Introduction of Nuns.

Some weeks ago the matron of the Cork South Infirmary resigned owing to ill-health and some of the Roman Catholic governors considered that members of a community of nuns should be introduced, one of whom should act as matron. The proposal came up for consideration at two meetings of the board of the institution and gave rise to considerable discussion. Though strong views were held on both sides the debates were conducted with decorum. The Roman Catholic view put forward by various speakers was as follows: that as 95 per cent. of the patients were Roman Catholics it was desirable to have religious consolation administered to them by nuns whilst due provision would be made for the Protestant patients; that the presence of nuns in the Cork Union Hospital had improved the moral tone of the inmates there; that the nun whom it was proposed to appoint as matron had already acted as a nurse at the union hospital and had received high commendation from the medical staff attached to that institution; that the services of four nuns, one of them to act as matron, could be had for £30 a year each without rations; and that the salary and rations of the last matron came to about the same amount—viz., £120 a year. On the other hand, the Protestant governors expressed the opinion that the matron should be one who had been specially trained in some large general hospital; that if a nun were appointed as matron Protestant parents could not be expected to send their daughters there to be trained as nurses; that no complaints had been made by the patients as to their treatment; that the spiritual wants of the patients were already freely provided for; that there were several Protestant subscribers; and that a portion of that support might be withdrawn. Eventually a vote was taken and four nuns of the Mercy order were selected, one to act as matron and three as assistants.

June 18th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Assassination of a Director of the School of Pharmacy by a Pharmaceutical Chemist.

A PAINFUL incident recently occurred at Nancy which has given rise to lively emotion among the various professors of the faculties. A pharmaceutical chemist, M. R. Four, killed M. Bleicher, the Director of the Higher School of Pharmacy. The facts of the tragedy are as follows. The Pharmacies Commission recently seized a sample of quinine from M. Four's establishment. On June 8th that gentleman, who was one of the best known pharmaceutical chemists in the town, received information that the result of the analysis of his quinine would be sent to the public prosecutor. This news made him quite silly. At 2 P.M. he took a revolver of large calibre, went off to the Faculty, and asked to see the Director. M. Bleicher received him, whereupon M. Four asked whether it was true that the result of the analysis was to be sent to the public prosecutor. M. Bleicher said "Yes," and M. Four promptly drew his revolver and fired at the Director who fell shot through the heart. On seeing the corpse at his feet M. Four shot himself through the head, expiring just as some of the lecturers who had heard the shots came rushing into the private room. M. Bleicher was 62 years of age and had only held the Directorship for one year. M. Four was only 45 years of age. At the outside he would only have had to pay a small fine or have been reprimanded by the authorities for having had on his premises quinine bought in bulk which was not up to the regulation alkaloidal strength.

The Blood-coagulating Principle of a Secretion of the Skin.

At the meeting of the Society of Biology held on June 1st M. Milian laid before the members the explanation of a fact which he had reported at the previous meeting—namely, the increased coagulability of the blood at the end of a hæmorrhage. It depends upon the secretion of a coagulating substance by the skin. The cells containing this substance are laid open by the puncture and thus allow their contents to escape. A demonstrative proof of this fact is afforded by ascitic fluid, which, although it does not coagulate spontaneously, yet does so rapidly on the addition of a small quantity of watery extract of skin. From these facts it would appear that the technique employed for clinical experiments upon the coagulability of blood is coarse and not to be depended upon. The results are in terms of the coagulating power of the skin and not in those of the coagulability of the blood. In hæmorrhagic diseases there exists together with the blood defect a tissue defect as well which may possibly be improved by appropriate serum treatment (*opothérapie*). Hæmophilia especially may be divided into two classes, a local "tissue hæmophilia," which is by far the kind most frequently met with, and a general hæmophilia having its origin in some condition of the blood.

Reforms in the Thesis for the Degree of Doctor.

Professor Pinard recently laid before the Faculty of Medicine a very interesting report upon some proposed reforms in the present system of presenting theses for the degree of doctor. His proposals are: 1. That the principle of the thesis should be maintained. 2. Every candidate offering a thesis shall choose his president and must also be accepted by him. The candidate must also have arrived at or beyond the sixteenth term from his matriculation. 3. The thesis which the candidate for the degree of doctor shall sustain must be a dissertation upon some subject relative to medical science. 4. The dissertation, whether printed or typewritten, must be in the president's hands at least one month before the date appointed for the reading and defence of the thesis. 5. The candidate shall deposit six copies of his dissertation with the faculty 15 days before the date of reading and defence. 6. The jury shall, abiding by the accustomed forms for the defence of a thesis, decide (*a*) whether the candidate's thesis shall be accepted; and (*b*) whether the thesis is worthy of being printed among the academical publications, in which latter case the candidate must supply the faculty with 200 printed copies. If the jury decide that the thesis is not worth publishing it shall remain among the archives of the faculty. It will be seen from these proposals that the principle of the thesis is maintained, but that certain restrictions are introduced which give an opportunity for discussion, not only at the Council of the Faculty, but also by the university and by the Minister of Public Instruction.

Absinthe Poison and other Toxic Essences.

At the meeting of the Academy of Medicine held on June 11th M. Laborde called to mind the baleful effects of absinthe and similar toxic essences. He asked that the Committee should consider the following terms of reference—(1) that without delay, in conformity with the motion put forward by Parliament, the committee in pursuance of its powers, should define those liqueurs, *apéritifs*, and drinks containing such essences as are most harmful to the public health, with a view to putting a stop to their manufacture, their distribution, and their sale; (2) that the study of the subject should be referred to the Committee on alcoholism; and (3) that any resolution which the Academy should pass after having heard the report of the Committee should be sent to the public authorities and to Parliament.

June 18th.

CANADA.

(*FROM OUR OWN CORRESPONDENT.*)

A Grave-robbing Case.

IN February last a third-year student of the medical faculty of Queen's University, Kingston, was arrested for having in his possession the body of a woman who had been recently buried. He was indicted on two charges: first that of having opened the grave, and secondly, for indecently interfering with a dead body. It was presumed that the body was for dissecting purposes, though this sort of material is not by any means a scarce article in the province of Ontario. On April 22nd he came up for trial before the judge of the county court of Peterborough, within which jurisdiction the alleged offence had been committed. On the first count the prosecution failed to prove that he had opened the grave, so the prisoner was acquitted on that charge. On the charge of indecently interfering with a dead body he was adjudged guilty and fined $200, or in default of the payment of the same to spend one year in gaol. For this the Ontario law provides five years in gaol or a fine at the discretion of the presiding judge. The previous good character of the defendant saved him from the heavier penalty of his act. This is said to be the first case of its kind to come before the Ontario courts and it is, therefore, interesting.

Honour for Dr. G. S. Ryerson.

The profession in Toronto and throughout Canada feel eminently gratified at the distinction accorded to Surgeon-Lieutenant-Colonel George Stirling Ryerson who has recently been made a Knight of Grace of the Order of St. John of Jerusalem in recognition of his distinguished and able services while Canadian Red Cross Commissioner to South Africa.

Canadian Nurses' Association.

During the session of the Dominion Parliament which has just come to a close one of the measures before the House sought to incorporate the Canadian Nurses' Association. Opposition developed against the Bill when it was first presented to the House Private Bills Committee. It was thought to discriminate against many of the smaller hospitals, including those in the West, and also against English and Welsh nurses who now carried on their profession in the Canadian North-West Territories. The Bill provided that a majority of the examining board should consist of physicians. The opposition, however, was so strong against the incorporation of the association that a motion to postpone it for six months was carried successfully. It is expected that the Bill will be re-introduced in the next session.

Sir William Hingston Honoured.

On May 6th there was celebrated at the Hôtel Dieu Hospital, Montreal, the fortieth anniversary of Sir William Hingston's connexion with this hospital as a surgeon. In this function his *confrères* on the staff, the sisters, the students, and the patients of the hospital all took part. The ceremonies began in the morning by the celebration of Mass in the chapel by Archbishop Bruchesi, after which the surgeons of the Hôtel Dieu presented Sir William Hingston with an address and an urn of great value. The medical students of Laval University were assembled in one of the operating-rooms, to which the party then repaired. Here another address was presented by the students to their esteemed professor, Lady Hingston at the same time being the recipient of a magnificent bouquet of choice flowers. By the sisters of the institution Sir William Hingston was presented with some relics which had been brought over from France over 200 years ago by Mdlle. Mance. In one of the large wards the patients were assembled, and in their behalf Dr. St. Jacques, the superintendent, addressed the distinguished surgeon, thanking him for his many years of professional labour and for his long service in connexion with the hospital. To all these tokens of appreciation he replied most feelingly in his usual happy and felicitous manner. Sir William Hingston has now reached his seventy-third year and is still actively engaged in the practice of his profession. His son (Dr. Donald Hingston) has been but recently appointed superintendent of the Hôtel Dieu Hospital in succession to Dr. St. Jacques who has resigned.

Bishop's Medical College, Montreal.

Recently a number of changes has been made in the teaching staff of this medical college and several new appointments have been made. Dr. F. W. Campbell will continue to act as dean and with him will be associated Dr. J. B. McCormell as vice-dean. In addition to his regular course of lectures in medicine and neurology Dr. Campbell will give a special course in insurance law, and the chair in medicine will be further assisted by Dr. J. W. Deeks, lecturer on internal medicine; Dr. A. J. Richer, specialist in pulmonary diseases; and Dr. W. Grant Stewart. Dr. Louis Laberge, health officer of Montreal, will take charge of the department of hygiene; while Dr. W. G. Reilly has been appointed to the chair of anatomy.

Western Hospital, Montreal.

The annual meeting of the Western Hospital, Montreal, was held in the latter part of May, when very satisfactory reports were received and adopted. The past year has been the most successful in the history of this hospital. In addition to lowering the debt from $10 000 to $8000 great improvements have been made in the buildings and new operating, instrument, and anæsthetic rooms have been fitted up with electricity and all the latest improvements. The report of the treasurer showed that the receipts had been $9381 91, and the expenditure $8944 79. The net assets of the hospital amounted to $99,458 The medical report, which was read by Dr. George Fisk, showed that in the outdoor department there had been 3500 consultations as compared with 3457 for the previous year. In the indoor department 396 patients were treated as compared with 380 for the previous year; there had been 24 deaths, or 6 per cent. If the eight who died within 48 hours of their admission were deducted the death-rate would only be 4 per cent. The average daily cost of all patients was 90 cents; of the public patients alone, 45 cents.

Montreal General Hospital.

Towards the end of May the governors of the Montreal General Hospital held their annual meeting, and, as usual, a deficit was reported. The General Hospital is now in arrears to the extent of some $25,000, having gone behind to the extent of $8000 within the past year. It has been decided to make a charge on and after June 1st of 10 cents a bottle for medicine in the outdoor departments for the first week and 5 cents thereafter. Dr. John McCrae was appointed resident assistant pathologist, and Dr. Von Eberts, the medical superintendent, has had his engagement extended for another year. His staff will consist of 10 house surgeons, with a lady superintendent and 70 nurses. Dr F. G. Finley, the secretary, reported that the expenditure had reached the sum of $84,280, and that the income had been only $75,994. The report of the medical work was as follows:—The total number of indoor patients treated to a conclusion was 2823, a decrease of one from the previous year. Of these, 175 remained from 1899-1900, and 2822 were admitted during the year. In the hospital at the end of the year there remained 154 patients. There were discharged 2573 and there died in the hospital 250. Of these 250 deaths 105 occurred within three days of the admission of the patients. The death-rate, therefore, had been 8 85 per cent., or excluding the 105 patients dying within three days of their admission, 5 12 per cent. The average cost per patient per day had been $1.37 as compared with $1 35 for the preceding 12 months.

June 1st.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Institute for Medical Research in the United States.

THE important announcement has just been made public that Mr. John D. Rockefeller has given $200,000 (£40,000) to found an institution to be called "The Rockefeller Institution for Medical Research." This sum, it is said, is only to be regarded as a preliminary gift, not intended as an endowment, but to be expended as the need may arise. A building will not be erected at any rate for some considerable time; work, however, will be commenced at once The first investigations undertaken by those connected with the institution will be to cooperate with the New York Board of Health in studying the milk supply and the contaminated article as a source of danger. In the autumn work strictly concerned with original research will be commenced. This work is to be carried on by the most prominent scientific men connected with the leading medical schools of the country, including Harvard, Johns Hopkins, University of Michigan, Columbia, and several others. The Board of the Rockefeller Institute will direct and control these investigations. The directors of the institute comprise the following well-known names:—President, Dr. W. H. Welch, professor of pathology, Johns Hopkins University; vice-president, Dr. T. Mitchell Prudden, professor of pathology at Columbia University; secretary, Dr. Emmett Holt, clinical professor of diseases of children at Columbia University; and treasurer, Dr. C A. Herter, professor of pathological chemistry at the New York University and Bellevue Medical College. The other directors are Dr. Theobald Smith, professor of comparative pathology at Harvard; Dr. H. M. Biggs, director of laboratories, New York Board of Health; and Dr. Simon Flexner, professor of pathology, University of Pennsylvania. These gentlemen have advised Mr. Rockefeller as to the best methods of starting the institution and have issued the following statement regarding it: "Through the generosity of Mr John D. Rockefeller an institution has been established to be known as the Rockefeller Institute for Medical Research. The purpose of the foundation, as the name implies, is to furnish facilities for original investigation, particularly in such problems in medicine and hygiene as have practical bearing upon the prevention and treatment of disease. The home of the institute will be in New York city, although, as will be seen from the make-up of the board of directors, medical men from neighbouring cities will share in its management It is not intended to build at once, but with the funds placed at the disposal of the board work will be begun under its direction in several different places The immediate aims of the board are twofold. First, to shape the lines of work along which the institute may wisely develop, both in contributing to knowledge and in the application of existing knowledge to humane ends. When this is done it is felt that such local habitation as the future of the institute shall require can be more wisely planned. It is understood that the buildings and equipment adequate to the wide scope of the institute and worthy of the humanitarian and scientific aims of the foundation will in due time receive consideration. The potential value of an institution of this kind and under such auspices [illegible] science and in the interests of humanity can hardl [illegible] are three features in regard to t [illegible] excellent augury of its success. These are that undoubtedly money will not be lacking; that the board of directors is composed of some of the foremost scientific men of the United States, whose presence on the board alone should be a guarantee that the work will be carried out thoroughly; and lastly, that the work has been begun in the right spirit. There has been no loud flourish of trumpets, but it has been wisely determined to proceed upon conservative lines, and when after a sufficient trial the directors have convinced themselves of the most efficient methods of developing the institution to put these methods into practice. Original research has long lagged in the United States, but it would appear that Mr. Rockefeller's gift may mark a new epoch in this branch of science.

Novel Sanatorium in Chicago.

A sanatorium is about to be constructed in Chicago upon a wholly new principle. The medical men in that go-ahead city have for some time been dissatisfied with the means of accommodation which Chicago offers to patients from a distance who are desirous of placing themselves under the charge of practitioners there. There are many objections both on the part of physicians and patients to the large general hospitals and it seems that there are no private hospitals in Chicago. In consequence of this condition of affairs those who wish to be treated in the city are compelled to betake themselves to large hotels or to apartments. The big hotels are too noisy and apartments have, as a rule. some drawbacks. Besides, friends or relatives of the sick have not always been able to secure quarters near the sick bed. To remedy this unfortunate situation it is stated that five physicians and surgeons of Chicago are preparing to build a large private hotel and sanatorium to cost $400,000 (£80,000). This combination of hotel and sanatorium is, it may be imagined, the first time that such a plan has been put into execution, and it is yet another tribute to the practical versatility of the Western American's brain.

Montefiore Sanatorium for Consumptives.

On May 30th a country sanatorium for consumptives in connexion with the Montefiore Home in New York city, a Jewish but non-sectarian institution, was formally opened. The sanatorium is situated at Bedford, a few miles from New York, and is constructed upon the most approved model for such institutions, while the treatment followed therein will be in accordance with the most modern methods. Vice-president Roosevelt and the Bishop of New York were the principal guests of the opening ceremony, each of whom made eloquent speeches. Some of the bishop's remarks were particularly to the point. He said in effect, "What are the causes of the misery represented here? It exists under the conditions under which men earn their bread. They pass their sleeping hours in homes that are unfit for human beings. Better the condition of the wage-earner and the home where he lives and you will have begun to deal with the great problem of civilisation. Then you will find a solution. Follow the trend of consumption where it was bred and disseminated. An ounce of prevention will be worth many pounds of cure." It was stated that the Montefiore homes in New York and Bedford give shelter and medical aid to 450 patients, to which the directors expect to add accommodation for 150 more unfortunates in the future. It was also stated that the two charities represent nearly a million dollars (£200,000) of capital and that the debt is only $50,000 (£10,000).

June 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Royal Visit.

THE visit of their Royal Highnesses the Duke and Duchess of Cornwall to Australia to open the first Parliament of the new Commonwealth is of all-absorbing interest just now, to the exclusion of all other affairs. The work of the ordinary medical practitioner in Melbourne is greatly interfered with owing to the stoppage of vehicular traffic in the streets and the enormous crowds that throng them on foot. Among the recipients of honours in connexion with the Royal visit is Dr. James Graham, mayor of Sydney, who is to be knighted. His career has already been referred to in these columns when announcing his election as mayor.

Prince Alfred Hospital, Sydney.

Reference has previously been made to the necessity for enlarging the Prince Alfred Hospital, and it has now been determined to erect new pavilions as a memorial to Queen Victoria. A public meeting was recently held to appeal to the public for subscriptions. The amount required over and above the amount given by the Government is £15,000, and £1600 was promised at the meeting. Dr. Charles Mackellar contributed £1000, with the stipulation that a ward should be provided for the treatment of soldiers and named in memory of his son who was killed in action in South Africa. The foundation-stone of the new buildings will be laid by the Duke of Cornwall.

Children's Hospital, Sydney.

The annual meeting of the Sydney Hospital for Sick Children was held on April 20th. The annual report showed that during the year 1900 there were admitted to the general hospital 421 patients, making, with the 42 remaining from the previous year, a total of 463. Of this number 284 patients were discharged cured, 68 were relieved, 25 were discharged unrelieved, 45 died, and on Dec. 31st there were 41 remaining in the institution. In the diphtheria cottage 117 were admitted, making, with nine remaining from the previous year, a total of 126 under treatment. Of these 112 were discharged cured, nine died, and five remained under treatment. In connexion with out-patients there were 9980 attendances of 2245 patients. In comparison with the statistics of the previous year these returns show a moderate increase. The death-rate in the general hospital was 10·6 per cent., as compared with 10·8 in the previous year. In the diphtheria cottage the death-rate was 7·43 per cent., as compared with 6·6 per cent. in the previous year. The out-patients' department showed an increase on last year of 544 attendances, but a decrease in the number of patients. The President (Mr. Justice Stephen) alluded to the pressing necessity for a new building and explained the difficulties about the site, to which reference was recently made in these columns. The medical report stated that owing to the want of accommodation in the present buildings 60 or 70 children with their parents or guardians were huddled together in the waiting hall, often some of them suffering from infectious diseases. One death during the year could be directly attributed to the insanitary condition of the building. It was also pointed out that a convalescent home in connexion with the hospital was greatly needed.

Sydney Hospital.

At the last monthly meeting of the board of directors of the Sydney Hospital Dr. W. Carnac Wilkinson resigned his position on the staff, as he had been appointed lecturer on medicine at the Sydney University. It was decided to thank Dr. Wilkinson for his past services. The following were re-appointed to their respective positions on the medical and surgical staff for a further period of four years:—Dr. T. Dixson, Dr. Fiaschi, Dr. W. H. Crago, Dr. J. McD. Gill, and Dr. Roland J. Pope. Dr. P. R. Kenna was appointed assistant aural surgeon.

St. Vincent's Hospital, Melbourne.

The annual meeting of St. Vincent's Hospital, Melbourne, was held on May 1st and was attended by an audience which completely filled the town hall and which expressed the most enthusiastic appreciation of the good work done by the hospital, £1000 being subscribed towards the building fund at the meeting. The number of patients treated during the year exceeded 10,000, an increase of over 1000 on the previous year. Reference was made to the exceptionally economic manner in which the institution was managed, the amount for wages being relatively insignificant.

Melbourne Hospital.

During the past year a little difficulty has arisen at the Melbourne Hospital with reference to the status and powers of the resident medical officers. On the election of the new resident staff for the present year they were called before the committee with reference to those difficulties. The newly appointed staff asked for precise information as to their authority with regard to ordering visitors, and especially ministers of religion, out of the hospital wards, and as to the arrangements to be made for dining. On the committee explaining their proposals the staff declined to accept them and resigned in a body. Subsequently a compromise was arranged and the staff resumed their respective duties. The position of resident medical officer has steadily declined in status during the last 20 years from a well-paid and responsible post to one with no salary and very little responsibility, little better than that of a resident dressership, and, indeed, apparently regarded as such by the committee who in the recent differences contemptuously referred to the members of the staff as the "students." The actual students also have a complaint against the committee for exacting extra fees for hospital attendance and also against the honorary staff for having, as is alleged, increased the fees charged for clinical instruction. The mode of collecting the fees has been altered and the scale revised. Formerly the method was somewhat complicated. Students paid certain fees to the University for clinical lectures and tutorial instruction to be given by members of the staff at the Melbourne Hospital and the Prince Alfred Hospital, and the University paid a certain definite sum annually to the respective staffs irrespectively of the amount received from the students, who also paid certain fees for hospital attendance to the staff direct and to the hospital. Last year the University council decided that all fees for clinical instruction should be paid direct by the students to the staff and the University would have nothing to do with the matter. The staff accordingly drew up a scale of fees, calculated on the amounts previously received from the University and the number of students receiving clinical instruction. At the same time the hospital committee increased the amount of fees payable to the hospital. The total increase in hospital fees for the course under the present arrangement is stated to be £36 and the total amount of fees of all kinds paid for the medical course is £190. The total fees at Sydney are stated to be £170 and at Adelaide £184, and it is maintained that the higher rate at Melbourne will compel students to go to other schools.

Sydney University.

Dr. E. J. Jenkins has resigned the position of medical tutor at the Sydney University and Dr. G. E. Rennie has been appointed to the vacancy.

Sir T. N. Fitz-Gerald, K.C.B.

The profession in Australia are very pleased at the honour of Knight Commander of the Bath conferred on Sir T. N. Fitz-Gerald of Melbourne for his services in the South African campaign as consulting surgeon. The recipient was specially mentioned in Lord Roberts's despatches.

Death of Dr. James Eddington Jefferies.

Much regret has been felt at the news of the death of Dr. Eddington Jefferies, late of Newtown, New South Wales, where he had practised for over 14 years. Dr. Jefferies was held in high regard both for his professional skill and his personal qualities. He was a well-known connoisseur in art and had a fine collection of pictures and china. His father is the Rev. Dr. Jefferies, formerly an eminent clergyman in Sydney, and now of Adelaide.

May 10th.

Obituary.

EDMUND BOURJONVAL DE LA CHEROIS, M.D. DUB.

DR E. B. DE LA CHEROIS met with his death as the result of a carriage accident at Sandford, Somerset, where he was on a visit to his brother. The deceased, after a course of study at Trinity College, Dublin, took the M.D. degree in 1890. Previously to his college career he studied at the Armagh School. The death of Dr. De la Cherois is much felt amongst the large circle of friends and acquaintances which he had formed in a practice extending over some eight years at Brighton. One writes of him: "He was always to be depended on to give a helping hand in all cases. His loss is great and he will not readily be replaced from a professional point of view. As a staunch friend and reliable colleague he had no equal." Dr. De la Cherois leaves a widow.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Langenbuch, Director of the Lazarus Hospital, Berlin. His published papers chiefly dealt with nerve-stretching and with the surgery of the gall-bladder and liver.—Dr. Hermann Baur of Giessen. He had published monographs on Dislocations of the Hip and on Congenital Absence of the Rectum.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation on June 13th Mr. G. V. Bull and Mr. J. L. Lock, Gonville and Caius, were admitted to the degrees of M.B. and B C.—At the congregation on June 18th the following medical degrees were conferred:—

M.D.—E. W. Ormerod, Trinity; C. F. Lillie, St. John's; and J. R. Charles, Caius.

M.B.—A. R. M. Brenan, M. Horne,* C. Killick,* A. E. Naish,* G. H. Orton, and G. A. C. Shipman, Trinity; F. E. Murray,* St. John's; G. E. Orme,* Caius, A. C. Pearson,* Sidney; and W. N. Heard, Downing.

B.C.—A. G. Wilson and J. S. Clarke, Caius; and those marked * above.

At the examinations for medical and surgical degrees, Easter term, the following candidates were successful in the subjects indicated:—

FIRST EXAMINATION.

Part I. Chemistry and Physics.—H. T. Ashby and F. A. Barker, Emmanuel; G. B. Bartlett and A. E. Bonny, Sidney Sussex; L. B. Cane, King's, C. Cassidy, Sidney Sussex; A. de C. C. Ch[illegible] G. [illegible] St. [illegible] A. [illegible] Jor [illegible] Gas[illegible] Goodhart and W. B. Gourlay, Trinity; A. C. Grant, King's; C. W. Greene, Emmanuel; R. E. V. Hale, B A., Caius; H. A. Hancock, non-collegiate; G. A. M Heydon, Christ's; E B. Hinde, Emmanuel; R. W. Ironside, Pembroke; R. S Jenkins, St. John's; C. N. Le Brocq, B A., Pembroke; R. McC. Linnell and W. B Marshall, St. John's; J. H B. Martin, Emmanuel; R. M. Miller, B A., Clare; A. W. Moore, Emmanuel; W. P. Morgan, B.A., Clare; F. H. C. Newman, Jesus; E. V. Culton, Christ's, A. S. M. Palmer, B A., *Jesus; D. G. Pearson, Pembroke; J. H. Pratt, Trinity;* R. S. Purkis, H. Selwyn; A. L. Singer, King's; K. S. Singh, B A., [illegible] Pembroke, [illegible] Ellison, Caius; [illegible] Elphinstone, Trinity; A. C. J Elwin, B A., Corpus Christi, M. F. Emrys Jones, Caius; [illegible] Trinity; G. B. Fleming, [illegible] lare; J. C. Fox, Trinity; [illegible] nmanuel; J. W. Grice, [illegible] lele, Emmanuel; A. L. [illegible] ius; G. A. M. Heydon, [illegible] B Hinde, Emmanuel; [illegible] rinity; C. N. Le Brocq, B.A., Pembrok[illegible] St. John's; S. [illegible] Marshall, St. [illegible] Trinity; W. [illegible] Jesus; A. H. [illegible] Palmer, B A., [illegible] Trinity; C [illegible] B A., and C. [illegible] G. L. Smith, [illegible] Downing, R. [illegible] St. John's; A. [illegible] P. C. West, B. [illegible] Pembroke; and [illegible], Christ's.

SECOND EXAMINATION.

Part I. Pharmaceutical Chemistry.—R. L. Barwick, B.A., Christ's; H. Beckton, M A., Clare; W. T. Briscoe, B A., H. Selwyn, H. A. Browning, St. John's, H. Cutler, B A., Clare; G. B. Davis, M A., Corpus Christi; G H. Drew, Christ's; A. H. Falkner, B A., Peterhouse; T. J. Faulder, B.A., Clare; H. J. Gauvain, St. John's; H. U. Gould, B.A., Trinity; G. F. Greenwood, Sidney Sussex, M. Gundry, St. John's; G. P. D Hawker, B.A., Caius; W. H. Hodson, Christ's; P. P. Laidlaw, J. W. Linnell and S. G. Macdonald, St. John's; J. Mellanby, B A., Emmanuel; H. W. Moxon and S. B. Priston, St. John's, J N. Robins, B.A., Christ's; H F. Skinner, Corpus Christi; J. M. Smith, Christ's; C. M. Stevenson, St. John's, B S. Taylor, M.A., Clare, C. B. Ticehurst, St. John's; B. Wallis, Trinity; N. Wilson, B A., Pembroke; H. P. Wiltshire, St. John's; J. L. Wood, Trinity; and R. F. Young, Christ's.

Part II. Human Anatomy and Physiology.—C. E. A. Armitage, B.A., Emmanuel; L. J. Austin, Sidney Sussex; H. M. Ariss, Downing; J. R. Beale and H. Beckton, M.A., Clare; G. F. Bird, B A., and H. J. D Birkett, B A., Trinity; E. M. Brown, B A., Pembroke; F. M. Bulley, B.A., Emmanuel; S. H. Clarke, B.A., Caius; A. W. D Coventon, B A., and W. L. Cripps, B.A., Trinity; A. H. Crossley, B A., Clare, S. H. Daukes, B.A., Caius; A. P. Day, B A., Christ's, L. H. Frankenburg, B A., Emmanuel; R. B. French, King's; F M. Gardner-Medwin, B A., M. F. Grant, B.A., and Everard Harrison, B A., Trinity; R. N. Hart, B A., Sidney Sussex, W. R. Higgins, B.A., Caius; H. F. Horne, B.A., King's; J. H. Howitt, M.A., St. John's; W. K Hume, B.A., Pembroke; F. A. G. Jeans, B.A., St. John's; A. E. Kerr, B.A., Christ's;

F. F. Leighton, B.A., St. John's; E. Lloyd, Emmanuel; H. F. Marris, B.A., Caius; W. L Murphy, B.A., St. John's; J. A. A. Orlebar, Magdalene; C. H W. Page, B A., Corpus Christi; F. W. M. Palmer, B A., Jesus; W. E. Paramore, B A., St. John's; N. C. Patrick, B.A., Christ's; M. C. M. Pitkin, B.A., non-collegiate; R. N. Poignand, B.A, Caius; R. Puttock, B A, Emmanuel; G. L. Ranking, B A, Pembroke; W. H. Rayner, Trinity; C. T. Y. Robson, M A., O L. Scarborough, B.A, and L. Shingleton-Smith, St. John's; E. Slack, Inc, Pembroke; B. H. Steward, B.A, Jesus; J. H. Trench, Trinity; A. C. Warren, B.A., Emmanuel; H. W. Wiltshire, B.A, Clare; F. L. Woods, B A., Caius; R. A. Worthington, B.A., *Clare.*

The Raymond Horton-Smith *Prize for the best* M.D thesis of the year has been awarded to W. L. Brown, M.A., M.D., of St. John's; *proxime accessit*, J. C. Muir, M.A., M.D., of Emmanuel.

Vaccination at Plymouth.—The vaccination returns for 1899, which have just been issued, show that during the year 3010 births were registered in the borough of Plymouth; of these 1681 were vaccinated, 11 were insusceptible, 491 died within 12 months unvaccinated, 13 were exempted on conscientious grounds, 86 cases were medically postponed, 33 had removed from the town, 284 could not be traced, and 411 were unvaccinated.

Seaside Camp for Working Boys.—An appeal signed by the Bishop of London, the Rev. Prebendary Ingram, Mr. E A. Ford, and Mr. F. Abel Bloxam, has been issued on behalf of the Seaside Camp for London Working Boys, which is in need of funds. This scheme of helping the working boys of London to secure a much-needed holiday has our hearty approval and we trust that the necessary funds will be at once forthcoming. The boys contribute towards their expenses, but it is utterly out of their power to provide all that is needed in order that they may receive a holiday.

Memorial to the late Mr. G. J. Symons, F.R.S.—A meeting of the subscribers to the Symons Memorial Fund was held last week in the rooms of the Royal Meteorological Society, 70, Victoria-street, Westminster. The treasurer, Dr. C. Theodore Williams, presided. The Executive Committee reported that the proposal that the memorial to the late Mr. G. J. Symons, F R S., the distinguished meteorologist and founder of the British Rainfall Organisation, should take the form of a gold medal had been approved and that the sum of £713 14*s.* 7*d.* had been subscribed for that purpose.

Royal College of Surgeons in Ireland: Barker Anatomical *Prize for 1902.*—A prize of £21 is offered for competition and is open to any student whose name is on the anatomical class list of any school in the United Kingdom. The preparations entered must be placed in charge of the curator before March 31st, 1902. The prize is offered for a dissection *showing the* distribution in the head and neck of the seventh, eighth, ninth, tenth, eleventh, and twelfth cranial nerves. The conditions under which the competition is to be carried out are as follows:—1. The preparation must be sent to the curator of the museums, Royal College of *Surgeons, each being marked* with a fictitious signature, and accompanied by a sealed envelope bearing outside the same *signature, and* containing within the full name of the competitor and a declaration to the effect that the work of the preparation has been carried out by himself. The printed form necessary *for this declaration* can be obtained on application to the curator. 2. The dissections are to be mounted in vessels fitted with glass covers, but the covers must not be sealed down. Earthenware basins and plaster-of-Paris *settings are* not compulsory if the specimens can be better displayed and *preserved by* other means. 3. No prize will be awarded unless sufficient merit be shown, 70 per cent. of the total marks being the minimum. The following *is the scale of marks*:—(*a*) for the merit of dissection, 60; (*b*) for excellence of setting, 20; and (*c*) for originality, 20; total number of marks, 100. Those dissections for which prizes are awarded *become* the property of the College. 4. Those competitors who enter dissections for which prizes are not awarded *but which show* sufficient merit may be refunded such amount of the cost of production as the examiners deem fit. 5. The cost and risks of transport must be borne by the student. The College will not be responsible for any damage that the *preparations* may sustain; but those of unsuccessful competitors residing at a distance will be carefully re-packed and handed to the carriers for delivery at such address as may be specified by the student.

The Pope has conferred the Cross "Pro Ecclesia et Pontifice" upon Mr. Francis Murphy, L.R.C.P., L.R.C.S. Edin., of *Tottenham, who, as medical officer,* was one of the gentlemen who took an active part in the great Jubilee *Pilgrimage* to Rome last year.

Hospital Memorial Bed.—The trustees of the estate of the late Mr. Frederick Rothwell have sent a donation of £1000 to the British Home and Hospital for Incurables, Streatham, S.W., to endow a "Rothwell" memorial bed in that institution.

The directors of the Great Eastern Railway Company have appointed Mr. William Rose, M.B. Lond., F.R C.S. Eng., senior surgeon to King's College Hospital, &c., consulting surgeon to the Great Eastern Railway, in the place of the late Mr. Thomas Bond, F.R.C.S. Eng.

Isolation Hospital for Llandaff and Dinas Powis.—An inspector of the Local Government Board held an inquiry in Cardiff on June 14th into the application of the Llandaff and Dinas Powis Rural District Council for sanction to borrow £8700 for the erection of an infectious diseases hospital.

Devizes Hospital.—The twenty-ninth annual meeting *of the subscribers to this institution* was held on June 13th. The medical report stated that 124 in-patients had been admitted during the year as compared with 118 in 1899, the average stay in each case being 34·8 days. The total weekly cost of each patient was 15*s.* 3*d.*, compared with 17*s.* in the previous year. The financial statement showed that the income amounted to £700 and the expenditure to £768.

A Plague of Rats.—At the Isle of Wight County Court on June 8th a farmer applied for a perpetual injunction to restrain two farmers, his neighbours, from continuing to allow the deposit on their farm in a large heap of the Newport town refuse, on the ground that it enticed and harboured thousands of rats, which had to a large extent destroyed plaintiff's crops on adjacent land. £50 damages were claimed. The case for the plaintiff was that the plague of rats did not commence till after defendants allowed the deposit and accumulation—*which had been going on for* two years—of nine loads per day of town refuse on their land close to plaintiff's property. The heap was soon swarming with rats, which overran plaintiff's land, eating nearly half of a four-acre field of oats, biting off some 4000 cabbage plants, hollowing out *a quantity of turnips* and mangels and honey-combing plaintiff's bank and filling a ditch. After evidence had been given his honour said that the defendants were not entitled to accumulate so much refuse beyond the ordinary requirements of their farm for agricultural purposes, and as the harbouring of rats was the consequence they were liable for the damage. He gave judgment for £35 damages, and granted an injunction, the latter being suspended for three weeks to give defendants time to remove the refuse.

Freemasonry.—*The Rahere Lodge.*—The installation meeting of the Rahere Lodge, No. 2546, took place in the great hall of St. Bartholomew's Hospital (kindly lent for the occasion by the treasurer and almoners) on June 11th. Mr. Sydney R. Scott, M.B. Lond., was initiated into Freemasonry and Bros. Waring, Cross, and Robinson were elected members of the Standing Committee. W. Bro. Gripper, M.B, the outgoing W.M., installed his successor W. Bro. Phineas S. Abraham, M.D., as W.M. for the ensuing year. W. Bro. Abraham then invested as his officers Bros. W. Gripper, G. *H.* R. *Holden*, E. Clarke, Rev. Sir Borradaile Savory, Bart., Clement Godson, D'Arcy Power, C. B. Lockwood, Haig Brodie, G. H. Gilbertson, Howard Marsh, A. G. R. Foulerton, G. H. Robinson, Mus. Bac., H. D. Lauchlan, M. J. Anderson, J. Valérie, J. Herbert Menzies, and P. F. Madden. A Past Master's jewel was unanimously awarded to Bro. Gripper for his services to the Lodge during his year of office, and presented by Bro. Clement Godson. Bro. Gripper, in reply, expressed his sincere thanks. A grant of 20 guineas was made to the British Medical Benevolent Fund. The report of the Audit Committee was received and adopted. It showed that the amount given in charity during the past year amounted to £69 6*s.* The banquet was held at Frascati's Restaurant and was attended by 86 brethren. A most enjoyable evening was spent, an excellent musical entertainment being provided by Bros. Courtice Pounds, Franklin Clive, W. L. Barrett, and others.

A MEETING of the Cambridge Medical Society was held on June 7th, Dr. J. Griffiths, the President, being in the chair. Dr. Nuttall read a paper on the Formation of Specific Anti-bodies in Blood, following upon Treatment with the Sera of Different Animals, together with their use in Legal Medicine. Mr. Young related two cases of Appendicitis followed by pelvic abscess in women past middle life, both of which made a good recovery without surgical interference, in one case the pus discharging through the bladder and the other through the vagina.

NORTH LONDON HOSPITAL FOR CONSUMPTION.—Mr. H. H. Asquith, K C., M.P., presided at a festival dinner in aid of the funds of the North London Hospital for Consumption, held at the Hotel Cecil on June 14th. In proposing the toast of the evening the Chairman earnestly appealed for funds to enable the hospital, which had been the pioneer of the open-air treatment of pulmonary tuberculosis, to make additional accommodation which was absolutely necessary to carry on the work of the institution. £6000 have been promised towards the building fund and donations have been received amounting to £2486.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY.—The Earl of Dartmouth presided at the Hotel Cecil on June 12th at a festival banquet in aid of the general funds of the Miller Hospital and Royal Kent Dispensary. In proposing the toast of the evening the chairman said that the hospital and dispensary ministered to a population of over 315,000, the majority of whom were dependent on charitable institutions in times of sickness. The institution was much in need of assistance, and if they were to provide in any adequate manner for those seeking admission the number of beds should be doubled. An additional £800 a year was needed for maintenance. The secretary announced during the evening subscriptions and donations amounting to £500.

KING'S COLLEGE HOSPITAL.—The annual festival dinner of this hospital was held in the hall of the Clothworkers' Company, Mincing-lane, E.C., on June 12th, when the Archbishop of Canterbury presided. The Primate, in proposing success to King's College Hospital, said that they must all wish prosperity to an institution where the health and comfort of human beings and the healing of disease were being studied and provided for. The century now past, especially the latter half, had witnessed greater progress in the science of medicine than any previous period, and King's College had worthily held its place in that progress. He referred to Lord Lister who had been so closely connected with that institution. King's College Hospital had a strong claim on all who needed or valued medical assistance, and it deserved the most liberal support. Donations amounting to over £2100 were announced.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JUNE 13TH

Medical Officers of Health in Scotland.

Mr. WEIR asked the Lord Advocate, as representing the [illegible] Scotland, whether, [illegible] health was require[illegible] would explain how [illegible] for Scotland only [illegible] ADVOCATE replied [illegible] health in the var[illegible] employed do not possess the qualification referred to by the hon Member because it was unnecessary in the case of appointments made [illegible]

Registrars of Births and Deaths.

Mr. GRANT LAWSON, Parliamentary Secretary to the Local Government Board, introduced a Bill to make uniform the law with regard to the [illegible] [illegible]strars of births and deaths. [illegible] s the boards of guardians [illegible] unions it is made by the [illegible] establish a uniform system [illegible]

FRIDAY, JUNE 14th.

A Standard for Milk.

Mr. HANBURY, President of the Board of Agric[illegible] that after carefully considering the evidence submitt[illegible] mental committee and their reports, he proposed [illegible] under which, for the purposes of the Sale of Food [illegible] as not genuine unless it con[illegible]ent. of non fatty milk solids. [illegible] pared, and he proposed that [illegible]

Enteric Fever among the Troops.

Sir WALTER FOSTER asked the Secretary of State for War whether he could state the registered accommodation of the *Mongolian* for troops and how many men she brought home from South Africa on her last voyage, whether there were seven deaths on board, and what was [illegible] for troops was [illegible] Yeomanry. There [illegible] miscellaneous diseases and other trivial cases during the voyage; 7 deaths occurred, all from enteric fever.

Medical Officers of Health in Scotland.

Mr. CATHCART WASON asked the Lord Advocate if, in the case of sparsely populated districts, [illegible] Islands of Scotland, the Government [illegible]n might be appointed officers of healt[illegible] sanitary science, public health, and [illegible]DVOCATE replied that the matter was entirely regulated by statute and the Government had no power in the matter.

Poisoned by Tinned Meat.

Mr. PARKER SMITH asked the Secretary of State for War whether he was aware that a number of men of the York and Lancaster Regiment in Fermoy barracks were poisoned on Saturday, June 8th, by eating tinned meat; whether he could state whether any deaths had occurred; from what source the meat was obtained; and whether a full inquiry would be made into the circumstances.—Lord STANLEY replied: Some men of the York and Lancaster Regiment were poisoned by partaking of a tin of beef This tin was purchased by the men from the canteen and was not part of the Government ration. The men are all practically well now. The commanding officer has full discretion in regard to canteen supplies and no inquiry is necessary.

MONDAY, JUNE 17TH.

State of the Concentration Camps in South Africa.

There was a long debate at this sitting of the House on the condition as regards sanitation and medical provision of the camps established [illegible] for the reception of Boer refugees. [illegible] for War, gave an account of the [illegible]rd to some of them statistics as to [illegible] the Johannesburg camp he stated [illegible]01, the deaths were six men, six [illegible]e said, were accounted for by an epidemic of measles There was an experienced medical officer in [illegible] to the sanitation of the camps and the treatment of their inmates, but Mr. BRODRICK said nothing about this suggestion.

The New Factory Legislation.

The Factory and Workshop Acts Amendment Bill was read a second time and referred to the Grand Committee on Trade.

TUESDAY, JUNE 18TH.

Proposed Amendment of the Medical Acts.

Sir RICHARD JEBB introduced the Bill formulated by the General Medical Council to amend the Medical Acts 1858 to 1886. It is safe to say that unless the Bill is practically unopposed it has no chance of passing into law during the present session.

Preservatives and Colouring Matters in Food.

Mr. WALTER LONG announced that the Departmental Committee on the use of preservatives and colouring matters in food have completed their inquiry and are now considering their report which he hoped would be presented during the present Parliamentary session.

Phthisis in the Post-office Service.

Sir WALTER FOSTER asked the Secretary to the Treasury, as representing the Postmaster-General, whether, in view of the scientific interest attaching to comparative statistics of mortality from phthisis, [illegible] master-General.

Strange Conduct of an Irish Medical Man.

Mr. WILLIAM JOHNSTON asked the Chief Secretary to the Lord [illegible] whether his attention had been called to the [illegible] O'Leary, C.C., at the Limerick petty sessions [illegible]t, on a charge of using threatening language

Notes, Short Comments, and Answers to Correspondents.

AN IMPORTANT POINT OF LAW.

AT the Folkestone County Court on Tuesday, before Sir William L. Selfe, judge, a case was heard in which a boarding-house keeper, named Nyren, sought to recover damages from a gentleman named Thomas, residing in Carmarthenshire, under the following circumstances. The defendant's daughter was at a boarding school at Folkestone and was taken ill. Arrangements were made for her removal to the house of the plaintiff, she being assured by the medical man and the schoolmistress that there was nothing infectious in the illness. Next day, however, typhoid fever was diagnosed and ultimately the child died in the boarding-house. There was an agreement entered into by the father as to the amount to be paid for rent of the apartments, &c., but he objected then to the payment of compensation The plaintiff sought to recover in all £32 16*s*, which included charges for disinfecting and for damage to linen and other articles, and also £16 for loss of business, a boarder who would have stayed for six weeks leaving her in consequence of the illness, and two ladies who would have taken apartments going elsewhere. The facts of the case were practically admitted, but the defendant's solicitor asked His Honour to take a note of the objection that the defendant was not legally bound to pay compensation inasmuch as plaintiff was running a risk in taking a patient into her house with a disease the nature of which she did not know, and should the defendant be legally bound to pay compensation the rent he was paying should be taken into consideration. His Honour, in giving judgment, said it was an important case, and one which would probably go further. The same point had been raised once before in his court at Folkestone, in a case in which the plaintiffs were hotel-keepers, but in that case he had no difficulty in dealing with it, because it was shown to his satisfaction that there had been no loss of business. (The case was reported in THE LANCET at the time) In the present case, however, it had been clearly shown that the plaintiff had lost business, and therefore he gave judgment for the £16, but disallowed sundry small items which he thought the defendant ought not to be called on to pay.

"HYPERIDROSIS. SUGGESTIONS WANTED."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 1st, p 1582, "Veldt" asks for some suggestion on the treatment of sweating on the least exertion. I refer him to the experiments of Dr. Ringer and Dr. Murrell with pilocarpine in small doses—viz., the twentieth of a grain The sweating in such cases is usually associated with nerve depression. Tabloids of the nitrate of pilocarpine are obtainable from Messrs Burroughs, Wellcome, and Co.

I am, Sirs, yours faithfully,

June 13th, 1901. M.D. ERLANG.

"THE SWALLOWING OF FOREIGN BODIES."

To the Editors of THE LANCET.

SIRS,—In your remarks on "The Swallowing of Foreign *Bodies*" in THE LANCET of June 15th, p. 1738, you suggest that diligent search may frequently discover the missing article about the house. The other extreme is, however, occasionally met with, as in my experience last Christmas An undemonstrative child, about four *years old*, was brought to me with a history of having had in her hand a halfpenny which, a moment later, was nowhere to be found. Coaxes, threats, and emetics were powerless to explain the disappearence and I had perforce to recommend a liberal diet of soft pappy food, with an assurance that the coin would become invested in it and pass safely *A month later* the watchful mother recovered from the motions *two* halfpennies—a very gratifying return in these hard times, panning out at the very respectable figure of 100 per cent. *per anum.* The father, a smart business man, regrets now that the child was not given a sovereign to play with!

I am, Sirs, yours faithfully,

West Bridgford, Notts, June 17th, 1901. H E BELCHER.

MEDICAL TESTIMONIALS TO QUACKERY.

A CORRESPONDENT sends us a cutting from the *Lancaster Observer* of June 7th containing a flaming advertisement of the skill and knowledge of one Siemms who describes himself as a "Specialist in Skin Disorders of the Feet and Hands, Surgeon Chiropodist." Mr. Siemms further informs his readers that he operates on all diseases *of the feet and hands* His fees are from 2*s*. 6*d*., but fungoid growths and varicose veins will be charged extra. Mr. Siemms quotes testimonials from four medical men. The first named, who according to the Medical Directory is M D., M.Ch. of the Royal University of Ireland, testifies to Mr. *Siemms's* skill in dealing with "several corns on the feet *of one of* my patients" The second testimonial comes *from* a M.D of London, with whose corns Mr. Siemms dealt "in a highly skilful and painless manner." The third testimonial is from a M.R.C.S, L.R.C.P., London, who considers that anyone may consult Mr. Seimms with confidence. Testimonial number four is from a M B, F R.C.S. Edin., who says that Mr. Siemms removed two corns from a patient of his to her entire satisfaction." Truly, a sour correspondent says, the medical men of Lancaster and district seem to be of a peculiarly trustful and unsophisticated nature. It is bad enough to give testimonials to a mere corn-cutter, but when it comes to medical men backing up an advertiser who has presumably had no medical education whatever and has no qualifications, who gives himself out as operating on all diseases of the feet and hands, it is time to protest Perhaps the medical men to whom we refer will offer some explanation of their remarkable conduct. At present we withhold their names.

A WARNING.

To the Editors of THE LANCET.

SIRS,—May I warn your London readers against a plausible American gentleman who calls and presents a card "Clarence Perry, M.D." He has a charming manner and says that he knows friends of yours in America who begged him specially to call and to present to you their respects. He calls again the next day and on a plea of urgency asks for a loan and offers to leave his watch or his ring as a guarantee of good faith. When he fails to come back to redeem the article it will be found that he has borrowed about twice its value. The police tell me that they cannot prosecute and I therefore venture thus to warn those who might otherwise be duped.

I am, Sirs, yours faithfully,

Harley-street, W., June 17th, 1901. JOSIAH OLDFIELD.

A BON MOT.

AT a recent medical gathering a speaker, to whose identity we will give no further clue than by saying that his name is known in connexion with removal of vesical calculi, happening to remark that in spite of competition and other circumstances he was glad to say he was not in the workhouse, was interrupted by one of his audience with the witty rejoinder, "You have to break stones, though!"

"KELÈNE."

To the Editors of THE LANCET.

SIRS,—If the writer of the question in THE LANCET of June 1st, p. 1582, as to Kélène and its usefulness will communicate with me I shall be very glad to tell him my experience of the drug. I have tried it in a fair number of cases now.—I am, *Sirs*, yours faithfully,

W. J. MCCARDIE.

54, Newhall-street, Birmingham, June 18th, 1901.

THE HOVIS CYCLE ROAD MAP.

THIS is a map intended primarily for the use of cyclists and also to advertise Hovis bread and Ariel cycles. As a map it is clear and good. The roads are marked in red and the quality of hills indicated by differently feathered arrows. Mileage is also marked. The map is on a scale of five miles to the inch and covers the whole of England and Wales, being divided into eight sections. That before us includes, roughly speaking, the S E. portion of England, its extreme points being from N to S., Oxford to the Isle of Wight, and from E. to W., Broadstairs to Kingsclere. Crockham Hill, near Westerham, is misprinted "Cockham." The price of the map is 1*s*, and a list of hotels, repairing stations, and the like is also given

◆

S. T.—A medical man may, in our opinion, give an anæsthetic for any dentist on the Register whether his registration is due to diplomas or to the fact that he was in *bonâ-fide* practice before a certain date. But a medical man should not assist an unregistered dentist by administering an anæsthetic for him.

Fulham.—We can only recommend our correspondent to give the matter no attention. Undoubtedly, if he could prove that he had been deliberately and publicly insulted he could obtain the protection of the law, but to bring an action upon flimsy grounds would be to expose himself to ridicule.

COMMUNICATIONS not noticed in our present issue will receive attention in our next

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "*London and Westminster Bank, Westminster Branch*") should be made payable to the Manager, MR CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Bristol Mercury, Bradford Observer, Brighton Standard, Pateley Daily Express, Leeds Mercury, Liverpool Daily Post, Yorkshire Post, New Zealand Times, Hertfordshire Mercury, Windsor and Eton Express, Mining Journal, Sanitary Record, City Press, Reading Mercury, Local Government Chronicle, Shanklin Gazette, Macclesfield Times, Standard, Australian Medical Gazette, Surrey Advertiser, Bulawayo Chronicle, South African News, Weekly Free Press (Aberdeen), Lancashire Daily Post, &c., &c.*

Communications, Letters, &c., have been received from—

A.—Messrs. Allen and Hanburys, Lond.; Messrs. Armour and Co., Lond.; Dr. A. G. Auld, Lond.; Dr. J. F. Armstrong, South Shields.

B.—Mr. Tom Bates, Worcester; Mons. C. Berthier, Paris; Messrs. J. H. Booty and Son, Lond.; Mr. L. Browne, Lond.; Messrs. J. Beal and Son, Brighton; Messrs. Bales Bros and Stevenson, Lond.; Bridgwater Infirmary, Hon. Secretary of; British Congress on Tuberculosis, Lond., Messrs C. Bayer and Co, Lond.; Burton on-Trent Infirmary, Secretary of; Messrs. An original and novel feature of "The Lancet General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in The Lancet.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

The Lancet can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Cavendish Lecture

ON

ACUTE CARDIAC FAILURE.

Delivered before the West London Medico-Chirurgical Society at the Town Hall, Hammersmith, on June 21st, 1901,

By Sir RICHARD DOUGLAS POWELL,
Bart., K.C.V.O., M.D., F.R.C.P. Lond.,
CONSULTING PHYSICIAN TO THE MIDDLESEX HOSPITAL, ETC.

Gentlemen,—"Acute heart failure" is, I admit, a misleading phrase, but it is scarcely necessary to explain to an assembly such as this that it implies, not any separate disease of the organ, but the culmination in temporary or permanent arrest of the cardiac function of a variety of conditions damaging to tension and exhaustive to nerve power or muscular energy. We cannot perceive aright the heart and its mechanism or appreciate duly its modes of failure unless we bear steadily in mind the fact that it is but a part, differentiated for special reasons, of a complete cardio-vascular tubal system containing the blood. The tubes are not passive tubes sluiced by a central force pump; on the arterial side the powerful rhythmic pulsations of the heart are so modified and restrained by the elastic muscular action of the vessels as to ensure a safe and adequate stream of blood throughout the body; whilst on the venous side the position of valves, the action of adjacent and often ensheathing muscles, the impetus of lymph and chyliferous tributary currents, and the constant but rhythmically increased thoracic aspiration help to maintain the blood movement.

I need only hint at the large influence of the nervous system which has in course of evolution become so specialised with regard to the heart and vessels. The cerebro-spinal nerves, the sympathetic system, and a department of the nervous system—the vaso-motor nerves—in touch with the preceding and yet under guidance from a separate centre, all take part in controlling the heart's doings and in regulating the blood-supply to each organ according to its functional requirements which vary from time to time. Finally, there is held in the tightening and relaxing grasp of this complex tubal apparatus the blood itself, a living tissue whose constant variations, both chemical and physical, in health and disease, affect the facility of the capillary flow and influence the tonicity and nutrition of the circulatory apparatus Can we look into this complex mechanism, which I have but enumerated, in which physical, chemical, and vital agencies are so intimately mingled, without a feeling of wonder that it should hold good unceasingly to the allotted term of life, and that so few lives should be brought to a premature close through heart failure? A chapter on compensatory adaptations has yet to be added to our text-books on medicine for our better understanding of many such problems.

With such an infinite number of contributory factors acute cardiac failure cannot be a simple question, and if I, bound by the stern limits of time and the more compelling limitations of my ability, approach it from the more concrete, clinical, and practical side, it is from no want of appreciation of the manifold intricacies of the subject, and it is with a very humble sense of our indebtedness as practical men to those whose patient labours in the laboratory have given us so large an insight to help us to solve the problems that come before us in our daily work.

A most obvious cause of heart failure is direct injury—excluding, of course, external wounds—as, for instance, the very rare occurrence in which a healthy man during some sudden effort ruptures one of his aortic cusps. The whole cardiac mechanism is suddenly put out of gear, severe præcordial pain, disorderly action, and faintness ensue, to be followed by other signs of perturbed circulation. In the only case of this injury that I personally remember seeing almost immediately there was smart hæmoptysis, no doubt from the over-distended left ventricle obstructing the return from the lungs. Under the only treatment possible—very complete rest—the heart, at first surprised and only very imperfectly able to deal with the altered mechanism consequent upon the spoiled condition of its main valve, gradually steadied down. The left ventricle enlarged and increased in power and the small, rapid, and irregular pulse was gradually altered to that having the characteristic features of aortic regurgitation. This alteration of pulse marked the adaptation of the heart to its new conditions in a manner precisely similar to that which we observe in a case of aortic regurgitant disease in which, dilatation of heart and mitral inadequacy having arisen, the irregular mitral characters of the pulse gradually return under rest and treatment to those proper and normal to a well-compensated aortic regurgitation.

The displacement of a clot from a systemic vein is a common cause of acute anginal heart failure and is attended with urgent dyspnœa, an irregular, fluttering pulse, and very variable heart signs. The condition is indeed one of asphyxia of the heart and it either terminates rapidly in death or the clot is further dislodged and propelled into the lung, when the cardiac symptoms quiet down and those of another order commence, with hæmoptysis significant of pulmonary infarction. Here, again, we can only recognise what is happening and relieve suffering and ensure quietude by subcutaneous morphia and like remedies. These cases are, however, by no means necessarily fatal; if the clot passes on to the lungs recovery ensues in a fair proportion and the prognosis in each case must be considered on its separate merits.

Next to such injuries to the heart, of which I have given a right-sided and left-sided example, we must glance at cardiac failure from over-taxation. There are two factors always at work, although in different proportions in different cases, in producing cardiac failure from great or prolonged exertion—viz., direct fatigue of the nervo-muscular tissue of the heart and a poisoning of the blood of auto-metabolic source. Speaking of young people and healthy hearts acute cardiac distress is, of course, very common in these days of athletic competitions, strenuous school exercises, hard bicycling, &c. It is surprising that actual heart failure so rarely occurs; but few of us have an opportunity of witnessing such an attack. Fatal cases are rare, but have been recorded. For the most part we can only observe the after-effects of incomplete heart failure.

Amongst the concomitants of heart distress or failure during violent exercise, as running, vomiting is one of the most common. A boy will tell you that at the end of a long race which over-taxed him he cast himself on the ground and vomited. Dr. Clement Dukes, speaking of boys overdone from running from various causes, says[1]: "Sometimes the boy will finish merely fagged or he will faint or vomit by the way and will require to lie down on the road, or he will complete his run, but vomit all the evening after reaching home; or, again, if still more overdone he may become absolutely insensible while running and this state may last for hours; or he may die whilst in the act of running." Amongst the after-effects one of the most constant is anæmia, and both of these phenomena, vomiting and anæmia, may be regarded as bearing witness to a changed condition of the blood consequent upon the accumulation of products of metabolism, which is now recognised as taking a not unimportant part in the mechanism of heart failure. I would remind you that gastro-intestinal attacks, vomiting, or diarrhœa are not uncommon occurrences in those who, habitually leading a sedentary life, suddenly take to exhausting exercise. There are other more certain proofs of altered blood in those who have died from excessive exercise and in hunted animals, of which increased liquidness of the blood, absence of post-mortem clotting, and darkened colour are amongst the more obvious. I am not aware of any observations that have been made upon the blood in healthy people after a period of training followed by severe and exhausting effort, and, still more interesting, after prolonged exertion in those who are not in training. We are all of us familiar with cases of neurasthenia and anæmia distinctly traceable to some severe exertion in a person with no previous training.

In estimating the consequences of over-taxation of the heart from violent or prolonged exertion in young people especially there are one or two points of practical moment to be observed. A glance at Beneke's tables[2] will show that the heart of the child is somewhat precociously developed, and this cardiac precocity is in accordance with what I believe to be a fact which I have long observed and pointed out in clinical teaching—viz, that the heart of the child, say, between six and 12 years is relatively hypertrophied—i e., the apex beat is somewhat to the left of the normal and the impulse relatively strong. This is the case especially with boys, and in my experience holds good with a considerable proportion of them. I have regarded it as due to the ceaseless activity of children and to a developmental precedence of heart to chest and lung capacity. The practical point is that I do not regard a slight extension of the apex beat within the nipple line, unaccompanied by confirmatory signs, as necessarily a morbid condition in a child. I look for the evidence of cardiac overstrain rather in an extension of the upper margin of dulness in the mid-sterno nipple line, an unduly perceptible impulse at the ensiform base, and in a hesitating action of the heart—i.e, an irregularity in rhythm and force. These signs in association with languor, anæmia, breathlessness on exertion, and sometimes a sharp pain at the heart which I have heard described as a "beastly pain catching the wind," caused by a slight effort are sufficient for diagnosis. You may get others, such as murmurs; you often do get a hæmic murmur over the pulmonary area, but murmurs are by no means essential or to be expected.

---

[1] Health at School, 1894, p. 331.

A foreknowledge of the contributory and direct causes of these preventable occurrences is, of course, of much importance, and, thanks very greatly to the labours of Dr. Clement Dukes and to the careful supervision of the able medical officers attached to most of our public schools of recent years and to the care with which boys are watched, weighed, measured, and their sports organised at most of our preparatory schools, all such risks are reduced to a minimum, whilst, on the other hand, the moral and physical advantages of athletics are fully maintained. A routine examination and registration of the health of every boy on entering school life would, however, be an advantage, supplemented, perhaps, by some brief form of health report from the home medical adviser.

A cardinal point—and the only one I shall touch upon—to be borne in mind with regard to young boys and girls is their special aptitude for short spells of active exercise but their complete unfitness for prolonged fatiguing monotonous exertion. This is almost the reverse condition applicable to older people, and it is one often forgotten, not, perhaps, so much at schools as at home. Athletic fathers, robust elder brothers, proud of the sporting alertness and eagerness of young boys, will often keep them out on long bicycle, golf, or shooting expeditions, and may thus cause grave damage to the young and rapidly-developing heart. There is certainly a lack of supervision of young men training for athletics at the universities, although it is true that they come already seasoned and tested from the public schools. There ought to be some medical "don" to supervise university athletics who should, however, be himself thoroughly in sympathy with the athletic spirit.

The treatment of acute failure of heart from overstrain involves a period of a few weeks' complete rest and often many months of careful supervision. Young people make a rapid and generally a complete recovery, provided no actual lesion has been produced The younger they are the more ready and complete the recovery. In youths and young men a degree of irritability of heart is often to be observed for many months, even for some years, the patient suffering from attacks of palpitation and cardiac pain on slight fatigue or exertion and often at night. Quiet exercise must be resumed after a time and it is, in my opinion, better to allow interesting exercises within measure, such as croquet, level cycling, golf, and easy tennis, rather than more formal courses of training. But each case must be considered on its merits. In some cases of cardiac overstrain in young people it will be found that a feeble lung capacity has led indirectly by imperfect pulmonary circulation to the heart distress. In such cases well-ordered respiratory exercises by developing the lungs will facilitate the work of the right heart and help the general circulation by increasing thoracic aspiration. Well-planned sea voyages or sailing trips from the coast are peculiarly advisable for adults, provided strict injunctions against smoking and all strong alcoholic drinks are given.

Another form of fatigue heart failure is that frequently met with in acute disease. It is too long a story for me to go into now. I have dealt with it with some minuteness elsewhere,[3] as met with under one of the most common of circumstances—viz., in acute pneumonia. It is met with also in enteric fever, in acute bronchitis in old people, during a severe asthma paroxysm, and in other conditions, such as functional tachycardia. The heart failure in these conditions may come about with a gradual quickening day by day of the pulse until it becomes fluttering, confused, running, representing little more than peristaltic movements of the heart. In other cases—and this more commonly in plethoric, fleshy, larged-framed people with a pulse at first not unduly quick, with considerable tension and accentuation of the second sound—the failure occurs quite suddenly, attended with rapid breathing, pallor, and cyanosis, sweating, collecting mucous rattles in the chest, and almost imperceptible running pulse. Under strong stimulation and the subcutaneous use of strychnine the patient may rally and all the conditions improve, but relapse often, and in elderly people almost always, takes place. An attack such as I speak of occurring in an old person with bronchitis or pneumonia is almost of fatal augury; the senile heart cannot recover the fatigue, and hence when the pulse mounts up to 120 in old people recovery is rare, unless the rapidity be attributable to functional disturbance from some temporary cause. With a sound heart in young persons no condition is too desperate for possible recovery.

Now to discuss the treatment of heart failure under these varying conditions would be to discuss the whole management of the illnesses in question. There are a few factors, however, in special concern with heart failure in acute disease—viz., (1) maloxygenated and otherwise contaminated blood-supply to heart muscle and nerve; (2) excessive weight of blood burdening the heart; (3) exhausted innervation from sleeplessness and physical cardiac fatigue; (4) positive obstruction to the flow of blood through the lungs; and (5) changes in the texture of the heart muscle incidental to the disease and especially to the pyrexia. Now the first two indications are undoubtedly met by depleting the blood volume from the venous side by attention to secretions, the occasional use of mercurials, careful limitation of the food taken in place of the over-feeding often to be observed, and in some cases a small blood-letting. The timely employment of oxygen inhalations at intervals through the day is a remedy of great value which ensures an improvement in the aeration of the blood sent to the left ventricle and so direct to the coronary vessels. It is by no means necessary to employ oxygen inhalations in the majority of cases of pneumonia, of which disease I am now especially speaking, but in all severe cases the cylinder should be at hand to anticipate the threatened heart failure. 3 and 4. Exhausted innervation and pulmonary obstruction are met with in pneumonia, advanced typhoid fever, and asthenia especially. Strychnia is the most powerful cardiac tonic we know and subcutaneously used is the best remedy for heart failure. In these cases, however, a frequent concomitant symptom is ballooning of the abdomen, and it is both dangerous and inefficient for the purpose required to give strychnia in such cases by the stomach. In asthma, pneumonia, and in enteric fever it is often possible in combination with the free use of oxygen and the occasional injection of strychnia to give a sufficient subcutaneous dose of morphia to procure some much-needed sleep. When the heart threatens to fail in asthma the paroxysm must be thus shortened. In bronchitis, on the other hand, under no circumstances can morphia be so given. I have often observed cardiac exhaustion threatened in asthma through the want of small administrations of concentrated and assimilable food essences at intervals to support the patient Alcoholic stimulants are, of course, often necessary, the dose being adapted to suit the individual case. 5. These changes incidental chiefly to pyrexia in the heart muscle as a cause of failure are mostly to be considered in the prolonged fevers and will be best warded off by a judicious mitigation of the pyrexia. I would only observe on this head that in cases where there are labouring action of the heart and a tendency to cyanosis and stagnation of surface blood I have seen much better results from hot-water than from cold-water sponging or cold applications. The surface circulation is facilitated, heat is rapidly lost, and the skin functions encouraged, all tending to lighten the burden of the heart. In the after-treatment of pyrexial diseases in which there has been prolonged rapidity of heart or any sign of heart failure a chief regard has to be paid to restoration from cardiac fatigue. Thus our level sea and country resorts are preferable to hilly places and exercise must only gradually and tentatively be resumed.

---

[2] Die Altersdisposition, 1879, p. 94.

[3] Lumleian Lectures: On Treatment in Diseases and Disorders of the Heart, Lecture III.

I can only glance at specific poison failure of heart in diphtheria, phosphorus poisoning, malignant anæmia, and the like, in which the cardiac nerves are directly poisoned, and in most cases a rapid fatty change in the heart fibres ensues. These cases are mostly fatal with the exception of the influenzal cardiac affections, amongst which symptoms of slowing and increased rapidity of heart are met with, also some most intense forms of angina, usually vaso-motory, and attacks of dangerous syncope may occur, yet the prognosis is even in severe cases, so far as my experience goes, as a rule, favourable.

Of anginal heart failure I have no time to speak at length. I would only urge that from a practical and treatment, as well as from a scientific, point of view we must regard angina pectoris as in the largest class of cases a functional disease—a cardio-vascular neurosis. In many cases it is dependent upon disorderly action of the vaso-motor nerves and is associated with a sound heart (angina pectoris vasomotoris). In many others we have a similar mechanism but with, in the background, an unsound heart—aortic regurgitation, aneurysm, senile fibro-fatty hypertrophy, coronary disease, and the like (angina pectoris gravior or secondary cardiac angina). In numerically a comparatively small although very important group the anginal failure is usually the consequence of cardiac degeneration secondary to coronary disease, sometimes to coronary thrombosis or syphilitic disease (syncopal angina or primary cardiac angina). It is obvious that all the causes of excitement, direct and reflected, of the sympathetic and vaso-motor nerves must be looked into in dealing with the larger proportion of these cases, whilst, on the other hand, any special form of cardiac lesion must be appropriately dealt with. In accordance with what has been above stated the immediate remedies for the cardiac attacks are of the anti spasmodic and sedative class, amyl, trinitrine, opium, directed against the arterial spasm which is so important a factor in the attack.

In cases of coronary lesion the employment of regulated exercises, combined resistance, and respiratory exercises, and, in old people especially, the regulated use of oxygen inhalation, will help to maintain cardiac nutrition for at least a time longer. Whilst gentle exercise calculated to raise the blood-pressure within the coronary circuit is thus to be advised caution is necessary that no cardiac fatigue be induced. The periods of exercise should be of short duration. As in old people with atheromatous vessels cramp in the legs is readily induced by any fatiguing exercise in consequence of the imperfect nutritional change allowed by the narrowed arteries, so we may similarly get cramp in the heart muscle which is very apt to prove fatal. This was pointed out by Allan Burns nearly a century ago and further dwelt upon by Sir Benjamin Brodie. It is to be noted also that the cramp of fatigued muscles does not necessarily come on at once, but frequently is postponed until the night Cramp in the leg is a mere painful incident, cramp in the heart muscle is apt to prove fatal.

There are two conditions leading up to heart failure which I have not touched upon and yet which from the remedial point of view are of immense importance, but they have been fully handled by my colleague Dr. Mitchell Bruce in his recent Lettsomian Lectures One is typified in the middle-aged, plethoric man who, working hard, lives too well and takes little exercise This man gradually acquires a fatigued and over-burdened heart, over-weighted with the heavy volume of blood which it has to propel He may get a spring or summer cleansing once a year at Homburg, Harrogate, or Carlsbad, but on the whole he drifts along often into irremediable disease of heart or kidneys or both His first introduction to the physician is often after an attack of breathlessness and cardiac excitement or failure occurring on some unwonted exertion, after which he remains perceptibly short-breathed. His cardiac area is extended, partly from a slight yielding but mainly from præcordial and interstitial fat. The first sound is weakened, often to extinction, and the second sound is labouring; there may be slight albumin or a little sugar in the urine. Under a depletory treatment, a restricted diet, with a limitation of fluids taken chiefly between meals, a great curtailment of alcohol and smoking, and well-arranged exercise, with insistance on deep, full inspirations from time to time whilst walking in the fresh air, such a man will be restored to health and practically rescued from some early catastrophe in the form of heart failure in acute illness or from drifting into chronic cardio-vascular disease. A few weeks' change away whilst getting inured to the treatment is of great value and such cases will derive especial benefit from Nauheim or modified Oertel treatment.

The other class of cases I would refer to in association with two causative factors—viz., nicotine and epilepsy. I may bring my remarks to a point and a conclusion by a brief sketch of a case in illustration. A captain in an infantry regiment was invalided home from South Africa on account of attacks of heart failure He was a married man, 37 years of age, had never had syphilis, but was an inveterate cigarette smoker. In July, 1900, whilst mounting a hill he felt distressed and on return to camp fainted, and after this he was unable to exert himself without some distress In September, having escorted some prisoners from Durban to Cape Town, without sickness or fatigue or any hardship, he on arrival was about to get ready for dinner and in the act of taking a glass of wine bitters when he suddenly fell down unconscious and pulseless so that a medical man who saw him immediately thought him dead. He remembered nothing until he woke at 2 A M. feeling very faint and ill. There was no preceding sense of faintness, no pain, and no convulsion. On a later occasion whilst feeling very well he suddenly fell unconscious for a quarter of an hour He has had one similar attack since his return home in November. He was subjected to a course of Nauheim treatment without benefit. His complaint was, besides these attacks, of almost daily attacks of cardiac pain, especially induced by any exertion. Dr Walker, under whose care he came subsequently to the Nauheim course, by rigorously restricting the tobacco and regulating his diet and stimulants, materially relieved these symptoms, and when I saw the patient with Dr. Walker in April the cardiac dimensions, position, and sounds were normal and the pulse, although feeble and rather quick, presented no other special feature. On inquiry into this gentleman's family history nothing cardiac was elicited, but it was ascertained that his second son was the subject of very frequent and severe attacks of petit mal and a brother was a deaf mute. This case was primarily no doubt one of anginal heart failure in association with excess in nicotine, and as such belonged to a class of frequent occurrence, but in the case just related the instantaneous attacks of unconsciousness were suggestive of at least an associated neurosis of an epileptic character. I have met with one very strikingly similar case in a younger man, also an excessive smoker, and I have a less full recollection of another case in connexion with excess in cocaine

I have from time to time been consulted about a lady who has long been the subject of night attacks of an epileptic character and who has recently developed marked and rather severe attacks of angina with heart failure of an alarming degree, many of which attacks usher in a mild epileptic seizure. In her case the pulse of late years has become extremely slow and she has presented some symptoms of myxœdema

Cases of cardiac hesitation with pulse of uneven rhythm not amounting to intermittency and presenting occasional attacks of fainting are not very infrequent amongst children, young boys especially, between six years of age and puberty. They are easily tired and are generally anæmic. It is quite exceptional to find them addicted to any secret vice There is nothing abnormal beyond altered rhythm and vacillating force to be found in the heart. The distinction between this form of heart failure and petit mal is often difficult and I am strongly inclined to regard the two conditions as allied. Removal from all mental pressure, an outdoor life, and arsenical tonics generally result in gradual recovery.

I have endeavoured in this address rather to suggest lines of thought than methods of treatment, feeling that you are as competent as I to give a practical therapeutic interpretation to whatever of my suggestions may meet with your acceptance

---

SOUTH-WEST LONDON MEDICAL SOCIETY.—The annual dinner of this society took place on June 20th at the Café Monico Nearly 40 members and friends sat down to dinner, Dr. M. G Biggs, the President, being in the chair. Among the guests of the society were Mr. Bryant, Dr. Habershon, Mr. Lockwood, Dr. James Taylor, Dr. Herbert Hawkins, and Dr. Morgan Dockrell. Some excellent music, provided by the generosity of Mr. T. S. Howell, a former President of the society, brought a very pleasant evening to a close.

Three Lectures
ON
THE PRACTICAL POINTS IN THE TREATMENT OF THREATENED ASPHYXIA.

Delivered at the Medical Graduates' College and Polyclinic, Chenies-street, W.C.,

BY ROBERT L. BOWLES, M.D. ST. AND., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE FOLKESTONE HOSPITAL; PHYSICIAN TO ST. ANDREW'S CONVALESCENT HOME.

LECTURE II.[1]

GENTLEMEN,—In my last lecture I demonstrated to you the nature of the experiments on which the Marshall Hall and Silvester methods for the resuscitation of the apparently drowned were based, and I told you that the committee of the Royal Medical and Chirurgical Society had confirmed in every detail the results of our experiments, and that the committee, in addition, demonstrated that in drowned animals, not only were the air passages choked with fluid more or less bloody, but that both lungs were highly gorged with blood so that they were heavy, dark-coloured, pitted on pressure, and on being cut exuded an abundance of blood tinged fluid with many air-bubbles in it. The committee up to this point made a distinct advance: it settled an important principle of pathology in a clear and definite manner. Before this time, although Sir John Simon and other pathologists had asserted the presence of water in the lungs in cases of drowning, the opinion of Sir Benjamin Brodie prevailed both in the profession and at the Royal Humane Society, to which the public always turn for advice in this matter. Sir Benjamin Brodie[2] says: "That the admission of water into the lungs is prevented by a spasm of the muscles of the glottis cannot, however, be doubted, since we are unable to account for the exclusion of it in any other manner; and a multitude of circumstances prove that these muscles form a sphincter to the windpipe as perfect in its functions as any sphincter in the body." The committee showed by their experiments, on the contrary, that Sir Benjamin Brodie's theory of the non-existence of water in the lungs was incorrect, for they proved that water did exist, at least in animals. Now, instead of showing how this water, of which they admit the lungs to be full, could be first removed and then replaced, *pari passu*, by the introduction of pure air, the committee advised the adoption of a method which would introduce the largest amount of air into *empty* lungs. I would ask how it was to be introduced into lungs shown to be already full of water. The only effect of forcibly driving in air, which the Silvester method certainly does, would be to drive the water forcibly forward into the minute bronchial tubes and into the air cells, giving rise to a spongy or doughy feeling instead of the natural light elastic crepitation of healthy lung-tissue. Moreover, the water becomes inspissated with mucus, and frothy, by mingling with the air remaining in the lung—an exaggerated condition of what I have elsewhere shown produces in apoplexy "mucous stertor."

It must have surprised the committee to have found their results, although confined to animals, so entirely opposed to those of Sir Benjamin Brodie, and caused them to wonder how such differences could have arisen. It occurs to me that Sir Benjamin Brodie and others at that time must have drawn their conclusions from the fact that at times in drowning no water was found in the trachea and larger air-tubes. This, however, could not be so surprising when we reflect how easily water will make its way out of the trachea and large tubes during the many and irregular movements to which the body is subjected whilst being removed from the water to a suitable place for treatment, and further when we reflect how rapidly water evaporates on exposure to the air. At all events, it is now quite certain that the previous observers were in error. In 1862 I had a case of drowning and observed it very carefully during the whole course of its treatment. I made it, in fact, the subject of an experiment and I found that for three-quarters of an hour a little fine white foam was expelled from the mouth or nostrils at each pronation of the body. A second case soon followed and my observation of it gave precisely similar results. I then critically examined the many cases of drowning reported by Professor Casper and in nearly all of them was to be found most positive evidence that the lungs of the apparently drowned were gorged with water. He says[3]: "In the recent bodies of those who have been suffocated by drowning we find, besides the cinnabar-red, vascular injection of the tracheal mucous membrane, sometimes only a few isolated, white, but very distinct, small, pearl-like bubbles; sometimes a much greater quantity of froth, which is generally white, and more rarely bloody, and sometimes the whole tracheal canal is completely filled with this finely vesicular white foam. This extends into the bronchi, or, rather, extends out from them and their ramifications, as is distinctly evinced by exerting strong pressure on the as yet untouched lungs, when this froth will be seen to ascend into the opened trachea, even in those cases in which little or none of it had been originally found." ...... "I have found," he says, "this appearance in the trachea [in those entirely submerged from the first], precisely the same as in those other cases in which a repeated emergence above the surface of the water, though not positively known, might yet have been supposed to have taken place. At all events, since this froth is the product of the mixture of the inhaled fluid, in which the drowning has occurred, of the natural mucus of the passages, or even of blood from some ruptured vessel with the air contained in the lungs and trachea, and caused by the final forcible respiratory movements, it must be regarded as an indubitable sign of vital reaction—that is, that life must be regarded as having existed at the period of its formation." The lungs completely distend the chest, "they appear to be inflated like a balloon, and are not like ordinary healthy lungs, tolerably firm and crepitating, but feel exactly like a sponge. A similar condition is not found so constantly after any other kind of death, excepting only the most acute œdema of the lungs, which, however, is not present in this case, and occasionally after suffocation in irrespirable gases. The distension of the lungs is in part an actual hyperaeria in consequence of the most violent inspiratory acts carried on at the momentary emergencies of the head of the drowning person above the surface of the water, but partly and chiefly a consequence of the inhalation of the fluid, in which drowning occurred, into the lungs, as has been indubitably proved by experimenting on animals with coloured fluids and by my own experience in regard to specific fluids. When the lungs are incised there is a copious outflow of sero-sanguinolent froth. The fact, proved by experiment beyond the possibility of a doubt, that the increased volume of the lungs does not exclusively depend upon mere hyperaeria explains why this condition of the lungs is found even in those cases of drowning where death has been caused, not by asphyxia, but by neuroparalysis, and this adds very much to the value of this most important appearance."

Such was the experience of Professor Casper and, it may safely be assumed, of the profession in Germany generally. Such, too, was the experience of the French School, as more recently confirmed at the Morgue by M. Bergeron and M. Montano. Dr. Taylor in his work on Jurisprudence, in quoting them, says: "The existence of a mucous froth in the fauces, larynx, and bronchi is, according to MM. Bergeron and Montano, the only constant sign of death by submersion, whether syncope or asphyxia preceded death." Mr. Blackett, the police surgeon of Hyde Park, tells me that in all cases of drowning in the Serpentine frothy fluid is found in the lungs. I attach much importance to the work of scientific observers who have devoted themselves to the study of forensic medicine, for they always work with the consciousness of great responsibility and of their statements being subjected to stringent criticism and cross-examination.

We have, then, arrived at this position: 1. It has been demonstrated that water always is present in animals that have been drowned. 2 I have adduced living cases and Professor Casper and other eminent pathological experts have shown in the dead that the same conditions obtain in man under similar circumstances. 3. I and others have observed and recorded cases in man in which frothy water continued to ooze away from the lungs for a long period during the application of the Marshall Hall method.

In 1861 a woman who had been taken out of the Serpentine and treated by the hot bath at the receiving house was taken to St. George's Hospital about one hour afterwards. Mr. Jones, the resident medical officer, stated that on admission "her breathing was fair, with loud rattling noise; her lips were livid, her pulse *very good*, her surface and extremities very cold; she was sensible and able to speak." Warmth and appropriate measures were employed but in half an hour Mr. Jones was suddenly summoned and only arrived to see her draw her last breath. The Marshall Hall method was immediately employed for half an hour without the slightest signs of recovery, but a large quantity of frothy fluid came from the mouth At the post-mortem examination next day it was reported that "both lungs contained an immense quantity of frothy fluid, the bronchi were filled with fluid and injected" In this case the lungs were loaded with, and paralysed by, water. There cannot be a doubt that the Marshall Hall method would have unloaded the lungs, but I cannot doubt, also, that had she been placed on one side on her arrival at the hospital the upper lung would have cleared and acted quite sufficiently to sustain life. A lung containing frothy fluid *does not* clear immediately; the bells of foam must gradually coalesce and ooze slowly away, and to assist this nothing is more adapted than the Marshall Hall method

Dr. T. Trollope of St Leonards was called to a man who had been taken out of the sea The man could speak a little and had vomited a quantity of water, but he rapidly became worse; insensibility ensued, the breathing became slow and faint, and the pulse flickering. The Silvester method was being used and Dr. Trollope persisted in it for some minutes. "Meanwhile," Dr. Trollope reports, "his respiration had ceased, beyond a slight mucous rattle in the wind pipe; his heart's action could not be felt; jaw clenched, and lips livid. ... .. I then, finding these alarming symptoms supervening in spite of the persistence in Dr Silvester's method, immediately had recourse to Dr. Marshall Hall's prone and postural or 'ready' method, and was gratified to find fluid escape from the mouth each time the body was laid on the chest, and respiration gradually set up, commencing with long drawn respirations, or rather gaspings, at intervals. I persevered in the prone and postural movements for three-quarters of an hour, till respiration was thoroughly and satisfactorily established. The man then again vomited between a pint and a quart of water, and was afterwards able to swallow a few tablespoonfuls of tea, and went on satisfactorily." A most characteristic illustration of what must always obtain in such cases.

In March, 1862, I was called to a man who had been knocked into the sea by a heavy chain. On getting him ashore he was believed to be dead, but one of the men thought "they ought to get the water out of him," and so proceeded to roll him from side to side, and whilst this was being done a quantity of water was expelled from the mouth and they perceived some attempt at breathing. A few minutes after this I was on the spot and found the man apparently dying, making occasional and feeble attempts to breathe, with a very feeble and irregular pulse. He was lying on his side with his head upon a coat, and a quantity of froth tinged with blood was lying on the coat in the neighbourhood of his mouth. I observed that clear water and froth welled out of his mouth at the end of every inspiration. Active friction of the limbs, hot bottles, and hot bricks were carefully applied to the body, and ammonia to the nostrils. Nearly an hour elapsed before we thought it possible that he could live. He then began to moan, and in a short time a small quantity of brandy was swallowed and he slowly recovered.

In July, 1864, a man was capsized in a boat at sea After being in the water for some time he was picked up and rowed ashore. On arrival he was cold and livid and was breathing with great labour. He was immediately turned on to his side by the coastguardsmen and a quantity of frothy fluid came from the mouth. He was taken to an inn, where he was kept on his side and where I saw him a quarter of an hour afterwards. He was then breathing with difficulty. A fine white froth, almost like milk, was oozing from his mouth and nose; his face was very livid, and meaningless in expression; his breath was cold; the pulse could not be felt There were a few moist râles in the left side of the chest, the side which was uppermost, but the breathing was tolerably free; the breathing on the side upon which he lay was very feeble and obscure, and moist râles were more abundant. He could not be roused. In half an hour he became a little restless, and then vomited a quantity of sea-water. The pulse could now be felt, but not counted; this gradually improved. Attempts at vomiting supervened, and there was occasionally a partial restoration to consciousness. After another attack of vomiting, the pupils, which had been widely dilated, became contracted, and he went off into a sound sleep. He passed a most trying night from restlessness and pain at the epigastrium, and the next day he was still livid but better and easier. The following day pleuro-pneumonia of the right side (that which was downwards) supervened. From this he slowly recovered.

The following extract from a letter from Mr. T. W. Colbeck of Dover is corroborative and worth relating: "Some years ago I had a case of drowning at the Sailors' Home in which I distinctly made out water to be present in the lungs, as there were loud mucous râles throughout both lungs. After long and persevering efforts with the Marshall Hall method I succeeded in resuscitating the man. During the whole period some water flowed from the mouth, much of it doubtless from the lungs, as it was very frothy. He had a severe attack of broncho pneumonia subsequently and was very ill, but from this he also finally recovered."

On August 11th, 1871, I was summoned to a case of drowning. I found a young man, about 19 years of age, lying on his back on the beach and men engaged rubbing his limbs The face was livid and there was froth about the mouth and nostrils, the eyes were open, the conjunctivæ were congested, and the pupils were dilated and fixed; there was no pulse, no respiration, or other sign of life. On percussion both sides of the chest were dull but less so in the subclavian regions The patient was turned on to his face and a quantity of clear water and froth issued from the mouth and nostrils; he was then turned on to his side and the Marshall Hall method was continued steadily for three quarters of an hour; up to the last a little froth issued from the nostrils when pressure was applied to the spine in the prone position. From time to time I examined the chest, and found the upper (right) lung gradually clear until at last it gave forth quite a natural resonant sound on percussion, whereas the lower lung remained perfectly dull. After using the Marshall Hall method for 10 minutes, when I thought most of the water had come from the upper lung, I had the upper arm (for the patient was kept on one side, the left, the whole time) raised up over the head, in the manner described by Dr. Silvester; more air now appeared to enter the tubes, and froth was, on compression of the thorax when the body was pronated, expelled. I could hear râles in the chest during the artificial respiratory movements. The face became less livid, and this was the only apparent change which occurred during our efforts The temperature of the body was sufficiently preserved by the heat of the sun. I had no galvanic apparatus at hand. On careful inquiry there is no doubt that the patient had been under water for 20 minutes for he was bathing half a mile from the town, and this distance had to be traversed and a boat rowed to the spot before assistance could be afforded. He was found near the bottom face downwards, in a sort of stooping position, and rose readily to the surface when an arm was placed beneath the body.

A case almost identical with the foregoing was under the joint care of Dr. W J Tyson and myself. The young man, aged 20 years, had been in the sea submerged for about the same time, the appearances were similar, a similar treatment was adopted, similar changes took place in the lungs during the treatment and the froth continued to ooze from the mouth about the same length of time. Both cases were carefully observed and although unsuccessful as regards recovery they may fairly be looked upon as experimental and scientifically accurate.

The following case has been kindly supplied to me by Dr. Tyson. A man, aged about 40 years, was brought into the Folkestone Hospital He had fallen into the harbour and was believed to have been in the water for from 10 to 15 minutes. On admission he was very cold and in a collapsed condition. There were feeble attempts at respiration. The Marshall Hall method was immediately applied and continued for 30 minutes During its employment the man was always kept on one side and was turned from face to side from 16 to 20 times in the minute. Sea water of a frothy character escaped from the mouth during each expiratory action for 20 minutes or longer. The man was manifestly better for the treatment adopted, but it was not considered safe to discontinue the artificial respiration for at least half an hour. The man eventually made a good recovery.

These examples, with many others that I could relate, show conclusively that in cases of *drowning in man water does exist in the lungs; that the water only very gradually*, and after a long time, is effectually expelled; and that it is absolutely impossible that efficient relief should be afforded in such a difficulty by the Silvester method alone. In 1863 I advanced another step, and in an experiment on a patient suffering from apoplexy with mucous stertor, demonstrated that it was dangerous to change the position of the patient from one side to the other, as *recommended* by Dr. Marshall Hall; for, after the patient had been lying on one side for a time, the mucus and fluids gravitated into the lowermost lung, and upon the patient being rolled over on to the other side, the mucous fluid found its way across the trachea to the opposite lung, and *on its way* had been whipped into foam by the ingoing air, which foam, *by* filling up the *larger bronchial tubes*, quickly caused suffocation of gradually increasing intensity. Other cases soon after occurred in which I was able, by experiment and by examination of the chest during life, to confirm the above observation, especially in a case of active hæmoptysis in which blood took the place of mucus. Of course, water, *slightly inspissated with* mucus, would necessarily follow the same course as blood on changing the side, and this I have fully proved does take place in cases of drowning. Further, in one case in which I did not allow the side to be changed, pleuro-pneumonia supervened on that side only which had been lowermost. The change of side, therefore, which Dr. Marshall Hall had originally advised to be adopted during the use of his method must on these grounds, *in future, be carefully guarded against.*

I had long become entirely convinced that the prono-lateral positions were the only positions to be depended upon in the management of these cases and that the removal of the tongue and epiglottis from positions of danger was a part of such management. The advice given by the committee in 1862 "to open the mouth and draw the tongue forward" again raised the question of the possibility of treating cases in the supine position. *I would refer to my account of our* experiments in the supine position in 1856 in which some obstruction was encountered in attempting artificial respiration on the dead subject, and I would quote the account of a dissection made by me at the time to ascertain the cause of the obstruction.[4] "On cutting down and removing the right side of the pharynx with corresponding halves of the hyoid bone and thyroid cartilage in another subject a good view of the position of the parts was obtained. The epiglottis was in direct apposition, by its laryngeal surface, with the posterior wall of the pharynx, so as to preclude the possibility of the passage of air. When, however, the head was allowed to hang backwards over the edge of the table, the bending of the cervical vertebræ caused the posterior wall of the pharynx to recede from the epiglottis, so as to allow the free passage of air. If the tongue had been drawn forwards, would the epiglottis have been removed from the pharynx, or would the prone position cause it to fall forwards?" It will be seen by this, and especially by the question asked at the end, that I at that time doubted the propriety of trusting to the pulling forward of the tongue as a remedy.

In my paper on Stertor[5] is another dissection of the pharynx, which besides "demonstrating the respective positions of the tongue with the opened and closed mouth, suggests the necessity of caution being used in raising the head with pillows; for if the head be too much bent forward on the chest the tongue may lie in dangerous proximity to the pharynx even if the mouth is closed." This observation applies to the lateral position in a minor degree, but more especially to the recumbent position; and I never fail to adopt in practice the teachings to be derived from these dissections. I further made sure by experimenting on myself that dragging on the tip of the tongue would not affect its base or the epiglottis sufficiently to make it a trustworthy procedure as it was checked by the frænum, so, as before, I was driven to conclude that nothing could be ever safely trusted as a remedy in apnœa drowning and comatose conditions whilst the patient was supine.

In 1873 Dr. Benjamin Howard[6] of New York presented an essay to the National Lifeboat Institution. In it he says: "The foundation of all true progress in the use of artificial respiration was first well and truly laid by Marshall Hall.' Dr. Howard had employed and taught both the Marshall Hall and Silvester methods, but in trying to obviate some defects which he found in them he took a new line of departure and advocated the employment of what he named the "direct method." He claimed for it greater exchange of air, greater facility and ease of application, and greater facility for the drainage of obstructive fluids, and says of it that it is more easy to be understood. You all doubtless know that this method consists mainly of pressure on the lower ribs in the supine position, the chest being elevated by a roll of clothing underneath the back so that the chest is on a plane inclined towards the head which is now at a lower level. Dr. Howard has shown clearly enough that no doubt should now remain in the professional *mind as to the existence of obstructions in the pharynx*, and that they must be removed and the effectual drainage of the lungs provided for as the first step in the treatment of the apparently drowned. I am not, however, prepared to admit that his method of carrying out the details of artificial respiration is the best possible. His objections to the Silvester method are evident and true, but his objections to the Marshall Hall method are neither evident nor true. In the Marshall Hall *method, slightly modified* to embrace the corrections of experience, we have, I believe, the best of all methods: (1) it is truly a very "ready method", and requires no apparatus; (2) the instructions are easy to be understood by ordinary unprofessional people; (3) on account of the immediate adoption and continued use of the prono-lateral positions this method is more to be trusted than any other for keeping the pharynx clear of obstruction; (4) *it empties the stomach and gradually* clears the lungs of the watery and frothy fluids and will surely and gently introduce sufficient air at each inspiration to take the place of the fluid which has been expressed; (5) the pressure applied to the back when the patient is prone exerts an influence on the heart, the blood is moved onwards towards the lungs which are, by the next movement, opened up to receive it, and thus the right side of the heart and the cerebral vessels are relieved of the engorgement which we know to exist; (6) the safety of the patient is more perfectly secured by keeping him on one side during the whole treatment, one lung being thus kept quite free; and (7) in apnœa, or, after a time, in drowning, when the upper lung is believed to be freed from water and frothy mucus, *if more air is required, it* can be introduced by elevating the upper arm above the head each time the patient is turned on his side, *an addition, in part, of the Silvester to* the Marshall Hall treatment.

A patient in a state of apnœa or syncope with greatly diminished circulation needs but little air for the preservation of life, and in drowning still less, on account of the presence of water in the lungs. It would be better to lay the patient on one side and to trust to nature alone than to have recourse to measures which would cause the forcible inspiration of air before the evacuation of water had been successfully effected. Artificial respiration, although undoubtedly the best and really only remedy when properly applied, becomes a *source of increased danger if used injudiciously and too violently. It is not necessary* in the Marshall Hall method to place a roll of clothing or anything else to elevate the chest when the patient is prone; we found by experiment that elevating the chest, even for a few inches, *when the patient lay on his face, caused expiration.*

You will observe, gentlemen, that I have not alone passed in rapid review the general question of drowning, but I have demonstrated some new principles upon which our future treatment of apnœa from whatever cause should be based—principles not theoretical, but which have stood the test of time and of experiment and have been already many times successfully applied in practice. *As an addendum and as* an illustration of the importance of being quite clear in our deductions from symptoms I will quote an observation made by Sir Benjamin Brodie[7]:—"In some instances, after remaining for a considerable time in a state of coma, *respiration is again suspended; so that if* recovery had been effected in the first instance by means of artificial respiration the animal may be said to die a second time. In others, although sensibility is restored, and with it the power of locomotion, it is only for a time; another attack of coma follows, and this is fatal. These statements are founded chiefly on experiments made on the lower animals, but there is no essential difference between the phenomena which occur in them and in the human subject. The case which I am about to mention justifies this observation. It was communicated to me by Mr. Rose, under whose care the patient was placed. *A boy of the name of William Claridge*, 17 years of age, attempted to hang himself on the evening of the 17th of July, 1820. He was discovered after a short period of suspension (the exact length of the period being unknown) and immediately cut down. He was at this time completely insensible; his face was livid, his lips were of a *dark purple colour, the pupils of his eyes were dilated* and motionless, his pulse not perceptible at the wrist. A pair of bellows being at hand, artificial respiration was immediately had recourse to. In about a quarter of an hour the diaphragm began to act. The artificial respiration was now discontinued. He breathed at irregular intervals, with *stertor*, and a *rattling noise*, from the *air passages being choked with mucus*. The pulse was now perceptible, but often flagging, and the surface of the body was disposed to be cold. The countenance was still of a livid hue, but the breathing became more frequent and regular, and there was also an improvement in the pulse. At the end of another hour an attempt was made to take some blood from the arm, but it was not successful; and from the coldness of the surface of the body it was thought expedient to place him in a warm bath. During the night he continued to breathe; *the stertorous breathing continued*. In the morning a vein was again opened in the arm, and 12 ounces of blood were taken away, but no relief followed. He continued insensible, cold on the surface, and *frothing at the mouth*, and died at the end of 24 hours from the time of his having been cut down. The body was carefully examined. The vessels of the brain seemed to be turgid, with dark coloured blood, but there were no other morbid appearances."

Transactions of the Royal Medical and Chirurgical Society, 1860.

[6] Lifeboat, Feb. 1st, 1873, p. 381.

[7] Brodie's Pathology, p. 70.

The case above related is an instance of what may be called secondary apnœa, and the cause of death is evidently looked upon by Sir Benjamin Brodie as some failure in the nervous system; whereas, from my observation on the causes and course of "mucous stertor," I am led to believe that death ensued in this as in other similar cases from bronchial suffocation, a sort of suffocative bronchitis, from neuro-paralysis from possible injury to the vagus, and that if the patient had been placed on one side and left to nature he might have survived. The patient was almost certainly drowned by his own mucus. With the exception that death in this case was subsequent to hanging and not to drowning it was, in its symptoms, almost identical with the case just related of the woman who had been conveyed from the receiving house on the banks of the Serpentine to St. George's Hospital and had there died from secondary apnœa.

In October, 1889, I was engaged with my assistant, Mr. John Stainer, in investigating the internal anatomy of the porpoise. On cutting into the trachea, which was strong and large (one inch in diameter) and completely surrounded by its cartilaginous rings, I was surprised to find it three parts full of sanguinolent spumous fluid. On squeezing the lungs, more frothy fluid exuded, and with it a number of slender white worms four or five inches in length The lungs themselves were dense and spongy, and here and there were cysts containing worms in embryo. From these conditions I inferred: (1) that the animal had been drowned in the element in which it lived; and (2) that its larynx must be closed or the fluid would have drained away or have been poured out or have evaporated during the many rough handlings the creature *had been subjected to since its death three days before*. Further inquiry and investigation corroborated these assumptions, for the animal had become entangled in a fishing-net deep under the water and was thus deprived of its breathing requirement, air, and brought up dead. On dissecting the pharynx from behind I found that the larynx passed upwards and forwards as a tubular prolongation far into the post-narial cavity and that about one and a half inches below its orifice it was encircled and firmly clasped and closed by the palato-pharyngeus muscle. It would appear that the laryngeal tube was, when in a state of rest, kept closed by this outside sphincter (the palato-pharyngeus), so as to prevent the untimely entrance of water when the animal was beneath the surface of the sea. The tubular portion was composed of the elongated cornicula or cartilages of Santorini above and the epiglottis in front and below, loosely joined together by soft expansile tissue and mucous membrane. The cavities of the mouth and nares were completely separated by the velum palatinum. The fluid extract from the bronchial tubes amounted to six drachms; it was of specific gravity 1026—precisely the same as the sea-water in which the animal had been drowned.

INTESTINAL SUTURE BY MEANS OF CONTINUOUS CATGUT STITCH AND EXCISION OF THE MUCOUS MEMBRANE.[1]

BY H LITTLEWOOD, F.R.C.S. ENG.,

SURGEON TO THE LEEDS INFIRMARY AND LECTURER ON PRACTICAL AND OPERATIVE SURGERY IN THE YORKSHIRE COLLEGE (VICTORIA UNIVERSITY).

IN surgery, as in many other arts, the nearer we approach simplicity the more nearly do we arrive at perfecting any method, and it is astonishing how many cumbrous and complicated apparatus we have to discard in arriving at simplicity of detail. After the revival of the operation of intestinal suture the earliest methods adopted were by means of a simple suture without the assistance of any special apparatus. Many cases of simple suture were successfully performed, still many were fatal. It was thought that one of the main factors in the success of a case was the duration of an operation. These operations were often performed at a time when the patients were extremely ill, when the disease from which they were suffering was far advanced, and when the methods of combating shock were not so well understood as they are at the present time, so that many appliances to expedite the operation were invented, beginning with Senn's plates and ending, so far as the present is concerned, with Murphy's button and La Place's forceps. Now the operations are done earlier, when the patients are better able to stand them, and we have many ways of combating shock—heated operating tables, strychnia in large doses, hypodermics of camphor and brandy, and large saline injections either into the veins, the cellular tissues, or the rectum; or if we are operating on cases of acute intestinal obstruction the obstruction is first relieved by means of a Paul's tube. This intestinal drainage relieves the obstruction and prevents any further intestinal toxæmia, so that at the end of two or three weeks the more serious operations of enterectomy or lateral anastomosis can be performed with a very good chance of success. At the present time many surgeons have reverted to the earlier practice and have abandoned the use of any special apparatus, and I am amongst those who believe that all accessory apparatus for intestinal suture will ultimately be discarded and that we shall rely on our fingers, the forceps, and needles and sutures. It is with this object that I wish to describe the method which I have lately adopted for intestinal suture in gastro-enterostomy, enterectomy, &c. During the last session of the Leeds and West Riding Medico-Chirurgical Society Mr. W. H. Brown read the notes of a very interesting case of gastro-enterostomy in which the opening had closed, necessitating a second operation which had been successful. Just before this I had witnessed the post-mortem examination of a fatal case of gastro-enterostomy in which the opening had become almost entirely closed by the union of the cut edges of the mucosa On thinking over these cases I determined to carry out the *following* details in performing intestinal suture. I venture to think that the method which I am advocating is worthy of further trial. I have done three successful colectomies and seven or eight gastro-enterostomies.

Gastro enterostomy —The abdomen is opened in the middle line, a suitable portion of the stomach is selected (either the anterior or posterior wall), and a loop of jejunum. These are now emptied and clamped by means of Doyen's pedicle forceps, the blades of which are covered with indiarubber tubing, and are held by an assistant so that the portion of the stomach and bowel to be operated on are in close apposition. The parts are surrounded with strips of gauze or flat swabs. An incision about one and a half inches in length is now made into the stomach and bowel through all the coats down to the mucosa, and then with a pair of ophthalmic scissors and forceps the coats all round are separated from the mucosa for a short distance, so that a broad surface of all these coats may be brought into contact. The posterior edge of the stomach incision is now stitched to its full extent to a similar portion of the bowel with chromic gut by means of a small curved Hagedorn's needle, the suture is knotted at both ends, and left long (Fig. 1). An elliptical portion of the mucous membrane is now excised from the stomach and a similar portion from the bowel and the parts are cleansed. The cut edges of the mucous membranes are now stitched the whole way round by a continuous stitch of catgut, knotting it at the two extremities of the openings so as to prevent its drawing too tightly and narrowing the opening. This done the anterior edges of the incisions into the stomach and bowel through the remaining coats are united by a continuous stitch, the same suture which was left long after uniting the posterior edges (Fig. 2). I am not careful to bring serous coat to serous coat, but I rather prefer to bring the deeper layers into apposition. The clamps are then removed. As a rule there is no bleeding—the stitching prevents this. It is important not to pull the stitches too tightly. The gauze is removed and the abdomen is closed. The actual cutting and stitching can easily be done in from 10 to 15 minutes.

---

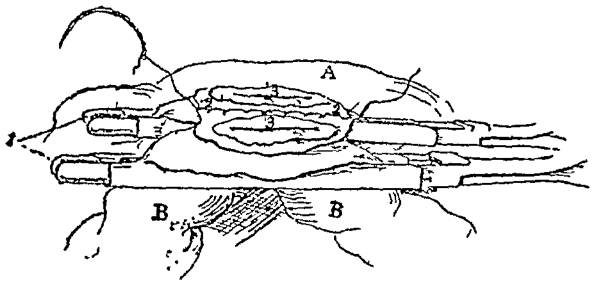
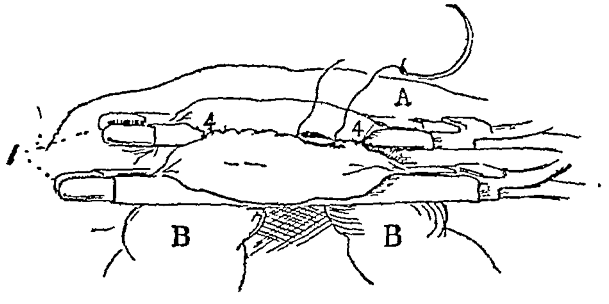
FIG. 1.



1, Doyen's forceps covered with rubber tubing clamping. A, Stomach. B, Jejunum. 2, Posterior edges of sero-muscular coats united with continuous catgut suture. 3, Mucous membrane excised from stomach and jejunum.

FIG. 2.



4, Anterior edges of sero-muscular coats united with a continuous catgut suture, the edges of the mucous coats having been sutured in a similar manner. 1 and A and B refer as in Fig. 1.

Enterectomy.—In doing enterectomy I perform a very similar operation. The parts to be excised are clamped above and below with Doyen's clamps and are removed with scissors. A portion of mucous membrane is excised so that it retracts beyond the cut edges of the other coats. This leaves a good broad surface for stitching. The two cut ends are approximated by the clamps and they are then closed by continuous catgut stitches in the same way as for gastro-enterostomy. Half the lumen, consisting of all the coats with the exception of the mucosa, is first stitched and fastened, then the mucous membrane the whole way round, interrupting and knotting the stitches in two places, and finally the remainder of the coats are sutured. The clamps are removed and the cut surfaces of the mesentery are approximated by interrupted sutures. The long handles of the clamps enable them to be held in such a manner that the hands of the assistant are well away from the field of operation.

I am indebted to my late house surgeon, Mr. F. Talbot, for the drawings.

Leeds.

A CASE OF ECTOPIC GESTATION WITH SEPTIC INFECTION OF THE GESTATION SAC.[1]

BY H. MACNAUGHTON-JONES, M.D., M.A.O., F.R.C.S. IREL. & EDIN.

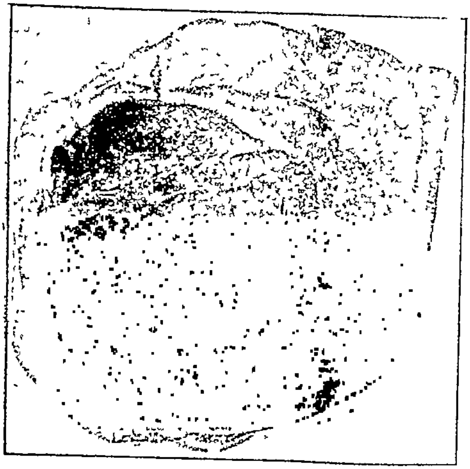
A PATIENT, aged 30 years, was seen by me in consultation with Dr. Alexander McDonnell of Stamford-hill towards the end of March, 1901. She had been married nine years, her only pregnancy being one at the close of the first year. The periods had been normal and regular up to Nov. 24th, 1900. On different occasions she had been treated for retroversion and prolapse of the uterus. On Dec. 10th, 1900, she was attacked with violent abdominal pain which passed off but recurred on Jan. 10th, 1901. The catamenia appeared on Jan. 24th. On the 29th there was a recurrence of the severe pain, which lasted for three days, when she passed from the vagina what she described as "a yellowish pink substance somewhat like the roe of a mackerel." She remained in bed for a fortnight and on Feb. 10th was able to go out of doors. On the 25th she was attacked with severe hæmorrhage, and again she passed portions of the same substance as before. Hæmorrhage and pain ceased until March 11th, when the former again recurred. On examination I found a fairly large tumour behind the uterus and associated with it, the uterine cavity being some two and three-quarter inches in length. Believing with Dr. McDonnell the case to be one of ectopic gestation and having regard to the size of the mass and the presence of adhesions, abdominal cœliotomy was determined upon and the operation was performed on April 1st. The adhesions were separated with but little trouble, but in the delivery of the sac through the enlarged abdominal incision a portion of the thin wall ruptured and some extremely fœtid fluid escaped, creating at the time quite a stench. The pelvic cavity was repeatedly cleansed with weak formalin solution, and as the bowel was well protected from the sac the only parts really affected, and this was unavoidable, were the margins of the wound. These latter were well wiped with 1 in 1000 of formalin before being closed, and an iodoform gauze drain was left in. There was nothing unusual in the course of the case for 48 hours, when the temperature rose to over 100° F. and the patient commenced to vomit. This, however, was controlled by an effervescing mixture. Sulphate of magnesia and calomel were given, both being retained, but without any result. Still, the temperature did not again reach 100°, nor did the pulse exceed 96 up to the fourth day. In the afternoon of that day, as the abdomen was distended and there was no result with enemata, while the vomiting recurred and the countenance did not improve, the pulse reaching 110, I determined to reopen the abdomen. On doing so I found the atonic bowel to be considerably distended but could not detect any kink or cause for obstruction. The pelvic cavity was quite free from any fluid and there was no evidence of any peritonitis or of infection of the peritoneum, but the margins of the abdominal wound showed a dense slough for its entire extent. There had been no indication of this from the appearance of the incision. The patient had complained of little or no pain from the time of the operation. The slough at either side was cleared off as far as possible and a drainage tube was inserted. As I had to leave home the same night Mr. Targett kindly took charge of the case for me. The temperature fell the next day to normal, but again it rose to 100° in the evening, the pulse becoming more rapid (from 120 to 140) with a return of the vomiting. Despite every means employed to combat the sickness and maintain her strength, including enemata, saline injections, washing out of the stomach, &c., death occurred on the seventh day after operation.

---

[1] A paper read before the British Gynæcological Society on June 13th, 1901.

In this case the temperature never exceeded 100 2° F. and there was an absence of the usual symptoms of general peritonitis. Mr. Targett reported of the specimen that it consisted of the right uterine appendages and a gestation sac, the latter being inclosed within the outer end of a dilated Fallopian tube :—

On section the wall of the gestation sac was found to be infiltrated with blood clot and fibrin, as in a tubal mole. Where suppuration has occurred the placental tissue is separated from the inflamed tube by pus, and chorionic villi are in actual contact with the inflammatory products. The mucous membrane of the tube is destroyed and replaced by granulation tissue. The tumour is roughly spherical in shape and measures 8 × 7 × 6 centimetres (3¼ × 2¾ × 2¼ inches) in its chief diameters after fixation in formalin. A portion of the posterior wall of the mass has been removed and reveals two cavities. The larger of these [illegible] is a space [illegible] Fallopian [illegible] with very [illegible] nearest to the uterus is the right ovary. The characters of the gestation sac are precisely those of an apoplectic or blighted ovum. It [illegible] mouth. The suppurating cavity, semilunar in shape, represents that part of the dilated ampulla of the tube not occupied by the gestation sac. From this relation it would appear that the tubal gestation had ended in a molar pregnancy or apoplectic ovum, and that secondary suppuration had been set up within the dilated tube and around the ovum. Consequently the pus had collected in that internal cavity which always surrounds a tubal mole owing to the ovum being adherent at only one spot upon the wall of the dilated tube.



Gestation sac with fœtus ; the upper cavity shown in the drawing is that in which the septic fluid was contained.

It would seem that the source of infection must have been through the adherent bowel. The patient having suffered from retroversion of the uterus the early symptoms might naturally lead to the impression that it was an enlarged retroverted and gravid uterus and tend to make the diagnosis less certain. From the size of the tumour and the impression which it conveyed of fixation by adhesions I determined on the abdominal operation, though, as events proved, considering the nature of the sac, the vaginal one would have been the safest one for the patient. Had I a similar case again, with rupture of a fœtid sac, having protected the bowel I should first char the margins of the abdominal wound with the thermo-cautery, and then at some distance from the charred surfaces make a new incision at either side before closing the wound. Not long since I opened the abdomen for a large and very fœtid subperitoneal abscess which had penetrated the peritoneum. Having evacuated the pus and thoroughly cleansed out the abdominal cavity with formalin, disinfecting the edges of the wound, which were covered by a foul and deep slough, I removed this at either side before bringing the edges together and drained. Contrary to my expectation the patient made an excellent recovery.

Harley-street, W.

ARE NOT SOME PATIENTS SAID TO BE AFFLICTED WITH GASTRIC ULCER REALLY SUFFERING FROM A DIFFERENT DISEASE?

BY W. HALE WHITE, M.D., F R.C.P. LOND.,
PHYSICIAN TO, AND LECTURER ON MEDICINE AT, GUY'S HOSPITAL.

IT is allowed that the malady commonly diagnosed as gastric ulcer is very much more common in women than in men; also that many more cases in women occur in the two decades from 20 to 40 than in any other two decades, whilst in men the disease is commoner later in life. Further, the mortality in men is higher than in women. For instance, Dr. R. Saundby has stated[1] that among 15 deaths at the Birmingham General Hospital due to gastric ulcer 11 occurred in men and four in women, a striking contrast when we remember the greater frequency of the diagnosis of gastric ulcer in women. Because of these facts I have for years been accustomed to teach that one of two conclusions must follow: either the outlook of gastric ulcer in women is much more favourable than it is in men, or many cases occurring in women and classified as gastric ulcer at the bedside are really instances of some other undescribed malady. I have also maintained that the second is the more likely view, for it relieves us of the difficulty of explaining the otherwise obscure facts that so called gastric ulcer is at its maximum frequency earlier in women than in men and is commoner in women than in men, although actually more fatal in men, and this view renders it more easy to understand why the condition diagnosed as gastric ulcer is so frequently associated with chlorosis, for this disease is almost confined to women and is met with at about the same time of life as that at which the diagnosis of gastric ulcer is most frequently made. I have therefore often suggested that there is a disease met with chiefly, or perhaps only, in women usually between 20 and 40 years old; that its chief symptoms are gastric pain, nausea, sickness, and hæmatemesis, that these symptoms are not dependent upon ulceration of the stomach, any ulceration that may be present being quite superficial and no more than might occur secondarily to the hæmorrhage; and that the diagnosis from genuine gastric ulcer occurring in women is very difficult, yet the facts that in spite of serious gastric symptoms extending over years the patient is not wasted, has been or is often chlorotic, and has none of the mechanical effects of gastric ulcer, such as adhesions, pyloric stenosis, or subphrenic abscess, may help us to a right conclusion.

The prognosis is entirely different from that of gastric ulcer, for, apart from hæmorrhage, these patients are not liable to the numerous serious complications of gastric ulcer. The prognosis is good, although relapses are frequent. Occasionally, but excessively rarely, the sufferers may die from hæmorrhage, and then no cause for it is found. The disease is in many cases, I apprehend, closely related to chlorosis, for it certainly is often associated with it or occurs in those who have formerly suffered from chlorosis, but it may, I think, exist apart from chlorosis. Until we know something of the cause of chlorosis we can hardly hope to know what the association is. I have not hitherto liked to put this view on paper for want of direct evidence in its favour, but now that surgeons have taken to opening the stomach for severe bleeding some support is forthcoming. Operators are already accustomed not to find an ulcer even when the hæmorrhage has been severe. Thus Mayo Robson[2] says: "If no ulcer be found anywhere and the bleeding proves to be capillary or from small undiscoverable ulcers." I take it that here we may assume that if the ulcer proves to be undiscoverable no ulcer exists. My proposition seems also to be supported by the following quotation from Mayo Robson[3]: "Erosions.—Of these Dieulafoy has described two varieties: (*a*) simple erosions, consisting apparently of mere abrasions of the surface epithelium, which, though so small as to be scarcely perceptible to the naked eye, may give rise to the most alarming hæmorrhage. On the post mortem table abrasions of this kind may be easily overlooked, but as seen when hæmorrhage is going on the mucous membrane seems to be studded with numerous bleeding points." This surely is a different disease from that which we know to be gastric ulcer, with its possible sequelæ of adhesions, sub diaphragmatic abscess, and other well-known complications, and it is surely more likely that the abrasions were the result, rather than the cause, of the hæmorrhage.

[2] THE LANCET, March 10th, 1900, p. 623.
[3] Brit. Med. Jour., Feb. 2nd, 1901, p. 257.

Byrom Bramwell[4] does not go so far as the proposition I am urging, but he does go as far as to say, "I am disposed to think that gastric ulcer in the young (chlorotic) female is on the whole a less serious and fatal disease than in men," and he proceeds to suggest that the reason is that in young chlorotic women the ulceration is superficial. I would go further and say that probably many of these cases in women are examples of a different disease, and I would suggest that as the ulceration even if present is superficial and trifling it may be secondary to the hæmorrhage. In other words, that the essence of the disease is not ulceration but a liability to gastric hæmorrhage independent of ulceration.

Dr. Newton Pitt kindly allows me to refer to a patient under his care, as she illustrates my point. She was a woman, aged 37 years, who for seven years had been liable to attacks of gastric pain, vomiting, and hæmatemesis. She was admitted into Guy's Hospital blanched and collapsed and died from hæmatemesis. The most careful examination at the necropsy failed to detect any source for the blood. The stomach was sent to the museum and the curator, Dr. Lauriston Shaw, failed to find any lesion of it.

Dr. Frederick Taylor also kindly allows me to mention the case of a woman who was admitted into Guy's Hospital under his care. She had for several years been seen by Dr. Lauriston Shaw as an out-patient for gastric pain, vomiting, and hæmatemesis The stomach was opened but no ulcer or source for the hæmorrhage could be found. The patient made an excellent recovery.

Cases can also be quoted from literature in support of my view. Thus Hirsch[5] records the case of a female domestic servant, 25 years old, who suffered from pain, vomiting, and hæmatemesis. The stomach was opened and as no ulcer could be found it was sewn up. The patient recovered completely. Armstrong[6] records the case of a woman, aged 35 years, in whom there was no definite evidence of ulceration, although the hæmatemesis was severe. The author reports that "no deep excavated ulcer was found, but blood was seen oozing from three different places which looked like linear fissures in two cases and in the third like a stellate fissure. Around the fissures over an area of one centimetre there was an apparent loss of superficial epithelium." Here certainly there was no definite ulceration; the changes, if they existed, were no more than might be produced by blood in bursting through the epithelium. Mansell Moullin[7] records the case of a woman, aged 34 years, whose stomach was opened on account of severe hæmatemesis. He says: "One very small bleeding point was found on the posterior wall of the stomach near the pylorus. It could scarcely be called an ulcer." Both Armstrong's and Mansell Moullin's cases, like that of Hirsch, recovered completely. Gilford[8] operated on a woman, aged 30 years, who had suffered severely from hæmatemesis for 15 days. Although there had been hæmorrhage all this time and the stomach was most carefully examined both inside and out no trace of an ulcer could be seen. She died nine days after the operation and then an ulcer three centimetres in diameter was found. This, Gilford says, was in a position in which it could not have been missed during the operation, and therefore this case is an example of severe hæmorrhage lasting 15 days, and yet when the stomach was examined with the greatest care no ulceration could be found. It does not by any means prove that the disease which I am describing naturally proceeds to ulceration; all it shows is that it may do so after the manipulation necessary to search for an ulcer. If subsequent experience should confirm this it clearly becomes important to diagnose, before operating, whether the blood proceeds from an actual ulcer.

As I have already mentioned, when the ulceration found by those who are earnestly seeking for it is trifling and superficial it is quite possible that it is the result of the hæmorrhage, for blood coming from the vessels into the cavity would naturally tear the epithelium. Thus Gilford quotes from Weir and Foote two fatal cases; in both the ulcer was so minute that it was difficult to find it when the whole stomach was spread out in a good light. In one of the cases its presence was positively shown only by transmitted light.

It has always seemed to me that as chlorosis is virtually confined to women at a period of high sexual activity the disease must be in some way connected with the function of reproduction, and I would suggest that the disease which I am urging should be separated from gastric ulcer is perhaps so connected, and in support of this I may recall the fact that many have considered that hæmatemesis may be vicarious menstruation and also the fact that these female sufferers may repeatedly come under observation for pain after food and hæmatemesis, but these symptoms wear themselves out before the menopause. Also, the association of this gastric ailment with chlorosis may, perhaps, be the reason for the frequency of the association of dyspepsia with chlorosis, for it may be that chlorotic dyspepsia is only a mild form of the same malady as causes severe pain after food and hæmatemesis, and in favour of this view I think it may be urged that severe dyspeptic symptoms are commoner with chlorosis than with other anæmias. My late house physician, Dr. A. E. Salter, acting on the views here expressed, has treated a large number of so-called gastric ulcers in young women with iron and good food and he finds that the patients do much better on this than on the usual treatment.

Lastly, I would call attention to the importance of separating gastric ulcer proper from this disorder, for the surgeon may find after he has opened the stomach that he can do nothing to control the hæmorrhage; some cases have died after operation, but the condition is of itself very rarely fatal. It is difficult to see how anything but harm can follow operation when the mucous membrane is studded with bleeding points; and, indeed, Mayo Robson[9] says: "Although the operative treatment of parenchymatous or capillary hæmorrhage by any surgical method would seem to be of doubtful value," and then he refers to five cases which died.

Harley-street, W.

FOREIGN BODY IN THE BRONCHUS; TRACHEOTOMY; RECOVERY.

By F. B. JUDGE-BALDWIN, M.R.C.S. ENG.,
SURGEON TO ROTHERHAM HOSPITAL.

IN following the history of foreign bodies in the bronchi the interest centres in the treatment, and that universally recommended is tracheotomy. This operation is called for firstly to lessen the danger from glottic spasm in the event of the foreign body moving and being coughed up; and, secondly, to afford a supplementary outlet for the foreign body itself. The further treatment consists in waiting for the development in the lung and dealing by direct operation with the possible—and probable—abscess that may arise. The following case adds one to the number of successes.

On Oct. 9th, 1900, a boy, aged five years, a very intelligent child, was coming home from school when he picked up a beech-nut, cracked it, put it into his mouth, and almost immediately began to choke. When met by a friend a few minutes afterwards he was still choking, his eyes were suffused, and his face was reddish-blue in colour. About an hour or so afterwards he was brought to my house because his voice "had gone husky." The breathing was rapid, averaging from 25 to 30 respirations per minute, with some stridor, and with whispering speech, though the speech was occasionally clear and the breathing free from stridor. I examined the larynx with the laryngoscope and found nearly complete bilateral paralysis of the adductors—i.e., the crico-arytænoidei laterales and arytænoideus—but no foreign body could be seen. The trachea was clear for some four or five rings and was not unduly vascular. On stripping the patient and examining his chest I found considerable deficiency of respiration on the left side over an area of the size of a five shilling piece, situated over the third rib about midway between the anterior axillary fold and the sternum, or rather nearer the former—in fact, the place of early phthisical development The respiration of the other lung was unduly exaggerated and the chest was heaving with insuction of the episternal and substernal spaces I sent him home with orders for him to be kept quiet in a warm room I saw the patient on the next morning when the respirations had increased to 32 per minute, the chest giving the same signs I suggested a second opinion and the patient was seen by Mr R J Pye Smith of Sheffield who gave the same opinion as myself We both agreed that tracheotomy was the proper treatment, but was not immediately necessary unless urgent symptoms should arise The same night I was called on account of a spasm which had subsided before my arrival Subsequently during the night the boy had further difficulty of breathing at intervals, but he slept when he was not so disturbed The next day I reported the condition to the consultant and it was decided to do the operation the same night (In passing, I might mention that the child's friends had turned him upside down during the night and had patted his back—a course I had not dared to venture upon He was very sick, but no foreign body was brought up)

[8] Guy's Hospital Reports, vol. liii.
[9] THE LANCET, March 9th, 1901, p. 688.

Before operation, which was performed at 6 P M on the 11th, the patient's temperature was 100° F , the pulse was 80, and the respirations were 40 The condition of the vocal cords did not appear to be a happy one for the administration of chloroform, and everything, therefore, was close at hand in readiness for an emergency which after a few whiffs of the anæsthetic duly occurred in the form of spasm and cessation of breathing, with coldness of the extremities Mr Pye-Smith quickly finished the operation, but even when the trachea was well opened no respiratory act ensued until after artificial respiration had been continued for some time The bronchi on the left side of the chest were well searched with long forceps, but nothing could be found The boy was then held up by the heels and some blood from the bronchi ran out A large tracheotomy tube was then put in and the opening in the trachea was further kept open by silver sutures with a loop through the cartilages, brought round and tied round the neck behind The boy was then put back to bed , he was warm and of good colour Three hours afterwards he was dozing The temperature was 100 8°, the pulse was 80, and the respirations were 40

At 6 A M on the 12th the patient was collapsed , his temperature was 101 8°, his pulse was 92, and his respirations were 44, with Cheyne Stokes breathing The tube was removed and cleaned There was considerable pain in the abdomen Milk and a sedative draught were given At 10 A M the boy was more comfortable , the bad symptoms were subsiding and he had slept 45 minutes The temperature was 101 4°, the pulse was 88 and the respirations were 40 The patient slept for eight hours during the night after coughing up much glairy mucus The temperature on the 13th was 100°, the pulse was 94, and the respirations were 36 Three days after operation (on the 14th) fluid food was taken well Some green tenacious mucus was coughed up The temperature was 99°, the pulse was 100 and the respirations were 32 On the 16th the patient had a comfortable day and night The stools were examined but no nut was found The temperature was 98 4°, the pulse was 100, and the respirations were 30 On the 17th the voice passed from a whisper, the respirations being 28 At 9 A M on the 18th two small bits of the husk of the beech nut were found on the dressing over the tube, which was removed The temperature was 99°, the pulse was 90, and the respirations were 28 On the 20th the temperature was 98°, the pulse was 96 and the respirations were 24 The chest was examined on the 22nd, when respiratory and vocal sounds were found to be deficient in the left lung over the pectoralis major close to the axillary border, otherwise the chest was clearing of rhonchi and sibilli which had been present since the operation The wound was healthy and the wires were removed On the 28th the patient came downstairs for the first time, his temperature being 97°, his pulse 84, and his respirations 20 The wound in the neck was not quite healed, but the boy was apparently well Since this time the chest has slowly cleared, but considerable weakness remained for some time At present one may say that nothing remains to remind him of his adventure but the scar of the tracheotomy wound

The interesting points of the case are, to my mind, the following It is well known that in children paralysis of the adductors takes place from slight causes, and on the face of it I was inclined to question the fact that a portion of the nut had gone into a bronchus Again, the condition of the child as to "cold" and possible false croup antecedent to the accident could only be cleared up by the friends, and as the patient had once before had some false croup a cold might easily be overlooked if not severe, while his general condition would favour croup These points must pass through the mind when considering the treatment and they were duly balanced The only direct evidence was that of the boy, that he had cracked a nut and had tried to swallow it The sudden oncoming of the attack favoured the presence of a foreign body and the treatment was subsequently proved to have been correct by the small bits of husk coughed up on the dressing I consider that the success of the treatment in this case was due in a great measure to the excellent nursing which the boy obtained

Rotherham

THREE CASES OF PUERPERAL ECLAMPSIA, WITH CRITICAL NOTES ON THE ETIOLOGY, PATHOLOGY, PROGNOSIS, AND TREATMENT.

BY J POLLOCK SIMPSON, M D GLASG

PUERPERAL eclampsia occurs so rarely in the experience of the private practitioner that it is desirable that all cases met with in practice should be put on record This may add to the value of experience already gained and may stimulate others to more careful and accurate observation by systematically examining the urine, which is the chief means we have of ascertaining the severity of the case, separating the para globulin from the serum albumin, and noting the relationship between the two as to quantity Herman has shown that the quantity of the former is greater in those cases where the patients recover, while in the cases of those who die the quantity of serum albumin is in excess

As regards the etiology of this disease many theories and hypotheses have been put forward to account for the convulsions—e g , the convulsions are the cause of the albuminuria—but in two of the cases described below (Case 2 and Case 3) I discovered the albuminuria before the convulsions were established—in Case 2 nearly three weeks before the eclampsia occurred and before delivery, and in Case 3 three days previously to delivery and the convulsions Of recent years a toxæmia or uræmia has usually been believed to be the true cause of this complication of the parturient state, at all events the convulsions are attended by a great *decrease in the elimination of* urea Whether urea is the actual excitant of the nerve centres or whether the excitant is a product of decomposition derived from urea has not been satisfactorily explained, but the uræmic theory finds the largest amount of support The accumulation of the toxins in the blood is due to the faulty elimination by the kidneys of the urea or waste products of *tissue metabolism* which are much increased in the pregnant state In nephritis these waste products accumulate rapidly, but pressure also contributes largely, and it is mostly in primiparous cases, where pressure and tension are greatest, that eclampsia occurs According to statistics 60 per cent of the cases of eclampsia occur in primiparæ Constipation, which is the rule in pregnancy, contributes in a great measure to this pathological condition

The following cases occurred in a busy practice with no assistance from trained nursing, as the patients belonged to the working class Notwithstanding the absence of those delicate attentions from a trained nurse—e g , passing the catheter and measuring the urine—so necessary to exact scientific observation and deduction, the patients all recovered and only one child was lost (in Case 1, which occurred at the seventh month) Nevertheless these cases have a value of their own, as in one case I was able to follow the history of the patient up to her second confinement with still a trace of albumin in her urine without any untoward symptom and she made a good recovery, In Case 1 the eclampsia was antepartum, in Case 2 it occurred in the second stage of labour, while in Case 3 the eclampsia was post partum following the delivery of twins In all the cases the result was successful and justified the treatment adopted.

Case 1.—The patient was a primipara, aged 23 years. I was asked to see her on Nov. 3rd, 1884, as she was said to be in a fit, which, however, had passed off by the time I reached her. She was seven months pregnant with her first child. On questioning her I found that she had gone out the previous day and had come home wet and with damp feet. Cold shivers had set in, so much so that the bed, as she said, shook under her. This was succeeded by violent headache, which the patient described as if the top of her head was being lifted off and on. On the day of my visit her face was noticed to be swollen; her legs were also slightly swollen, but later they became very brawny, especially after her convulsive seizure. She could not recall any of the events of the day. I put her on a mixture of bromide of potassium and chloral hydrate. Next day (the 4th) she had four or five slighter seizures and did not feel at all well; indeed, she was so ill that the question of induction of labour was discussed, but this was put off till the morning of the 7th, when she had the premonitory symptoms of another seizure, for which chloral hydrate (20 grains) was given, and then I introduced an ordinary gum elastic bougie into the uterus and allowed it to remain *in situ* till labour pains began, nine hours after its introduction, at intervals of 15 minutes. Next day the pains were rather better and I withdrew the bougie. In the evening there was a slight show of mucus when I made a vaginal examination and found the bag of membranes protruding between the lips of the os, which was of the size of a florin, but as the pains were not very vigorous I re-inserted the bougie which accelerated the pains considerably. I was called at 5 30 A M. on the 9th and found on examination per vaginam that the membranes were ruptured and that the breech was presenting at the vulva. I completed the labour, the child being dead when delivered, and the placenta was easily expelled by expression. The child proved to be a female of seven months. The urine on the third day was very scanty and highly albuminous. Its specific gravity, taken on the fourth day, was 1012, and after delivery on the 9th 1020, on the 10th 1023, and on the 12th 1030. The swelling of the face and legs disappeared rapidly after delivery, but the urine was still loaded with albumin on the 12th, otherwise the patient made a good recovery, only complaining of backache and occasionally slight headache. On March 27th, 1885, she was put on tincture of perchloride of iron (five minims), which she continued to take for nine months off and on, but the albumin had not quite disappeared, amounting to a well-marked ring, at her second confinement, which occurred on March 6th, 1886, when she was delivered of a fine, healthy boy without a bad symptom. There was no tendency to flooding either at the first or second confinement, which Spiegelberg says is usual.

Case 2.—The patient was a primipara, aged 21 years. On March 3rd, 1886, I received a communication about this patient relative to the swelling of her legs and feet. I found her complaining of occasional headache, dimness of vision, and giddiness. The urine was scanty, but there was no pain on passing it. She had not noticed any swelling of her face or puffiness, but her mother had noticed it to exist underneath the eyes. She ate heartily, enjoyed her food, and slept well. She had been sick two days previously for the first time since becoming pregnant. The urine was light-amber-coloured, and on testing it with nitric acid it was found to be loaded with albumin. The specific gravity was not noted. I put her on tincture of perchloride of iron and solution of acetate of ammonia. On the 13th the specific gravity of the urine was 1020, and it was loaded with albumin. The swelling of the legs was much the same, but the patient's sensations were better, and she thought that the medicine had removed her headache. I received a message on the 22nd to say that she was in labour. On arrival, at 10.50 A M., I found her walking about; the pains were infrequent and not very strong. On examination per vaginam I found the os nearly fully dilated, with a head presentation; the membranes were ruptured and the waters had drained away. She complained of headache. The bowels were open. At 2 P.M. the labour was more advanced; the anterior lip of the os was very œdematous. The patient still complained of headache. At 3 45 P M. the vertex was much lower. As she was lying on the bed I noticed a slight twitching of the right arm which her sister, who was nursing her, thought was shivering, but I at once saw that she was going to have a convulsive seizure. I seized my forceps at once, but before I had time to apply them she was in a strong convulsive fit, her face being drawn up into a sardonic grin; she was blue in the face and struggling for her breath, every moment appearing as if it was to be her last. I at length got the forceps adjusted with little effort and proceeded to extract the child as quickly as safety would permit. By the time I had the head extracted the worst part of the fit had passed off, and I extracted the trunk easily by pressure on the fundus. The child was a female; she was strong and vigorous and cried lustily. The placenta was easily expressed. The patient, having recovered somewhat from the fit, complained loudly of pain. She was semi-conscious, there was no excessive hæmorrhage, and the pulse was 120. When I left her, half an hour after delivery, she knew who I was, but the headache was still severe. I immediately received a message to the effect that she was in another fit; but on my arrival it had passed off, and she was quite rational. This seizure was not quite so strong as the first. I called at 11 P M., and found that she had had another fit which had lasted for 10 minutes, but that she had had two hours' sleep since, and she was still sleeping at the time of my visit. The pulse was 115. On the 23rd at my visit, the patient was asleep. The pulse was 112, the face was puffy and swollen, and she complained of severe vertical headache. She had passed no urine since delivery; I therefore drew off one and a half pints of urine, which was straw-coloured, and she felt easier. At 11 30 P M. the patient was awake and cheerful, the pulse being 114 and feeble. I drew off about a pint of urine. On the 24th she expressed herself as feeling better. Her headache was less and she passed a considerable amount of urine which was paler in colour, with a good deal of sediment (urates). The lochia were not offensive. The pulse was 102. The specific gravity of the urine was 1025; on boiling it, it became almost solid, it contained crystals of urate of soda and tube-casts in abundance, both granular and hyaline. At 11 P.M. the patient was better, her headache being only slight, and she partook of nourishment freely, her pulse being 107. On the 25th the pulse was 106, the temperature was 101·8° F., and the general condition was good. The bowels were relieved at 11.45 P.M., when the pulse was 100 and the temperature was 100·4°. On the 26th the headache was more frontal, the pulse being 105, the temperature 100°, and the lochia were slightly offensive. Headache was still persistent on the 27th, when the pulse was 99 and the temperature was practically normal. The specific gravity of the urine was 1028 and the albumin was greatly diminished. On the 29th the patient had a relapse from having got out of bed, and there was a tendency to syncope. The pulse was 105, and the temperature was 99·4°. The urine was scanty and there was an increase of albumin. Its specific gravity was 1030; it was darker in colour and it had a smoky appearance. On the 30th the headache was still persistent, the pulse being 106, and the temperature 99·8°. From this time on till April 30th, when I ceased to visit her, the patient's condition varied. She would have headache one day which was gone the next. The temperature was variable as well as the urine, which at my last visit still contained a trace of albumin, its specific gravity being 1020.

Case 3.—The patient was a primipara, aged 23 years, who was delivered of twins on Oct. 21st, 1894. Three weeks before this occurrence the patient had noticed some swelling in her feet and legs, but she took no particular notice of it as she thought that it might be due to the pressure of the child. On the 18th she had noticed for the first time that her face was swelling. On the 20th I examined a specimen of urine and found it to be loaded with albumin and solid on boiling; its specific gravity was 1025. On the 21st I received a message to attend the patient. On arrival I found, on examination per vaginam, the os to be of the size of a crown-piece. The waters had all drained away. The case proceeded slowly for five hours when the vertex was on the perineum, and as the pains were feeble I applied forceps and extracted the head easily and without the signs of a convulsive seizure. When the child was fully born I discovered a second child in utero. As the bag of waters protruded through the vulva I ruptured it and extracted the second child in the same manner, the after-birth following quickly by slight expression without any signs of convulsions, and I began to think that the worst was over. The pulse was 136 and the temperature was 100·8° F. About one and a half hours after leaving her the husband called to say that she had been having fits almost from the time that I had left her. I prescribed a draught containing chloral hydrate and bromide of potassium, and as I had another primiparous case in hand I left her, my assistant watching the case for me. When later I was able to see her I found her insensible, the pulse being 128 and the temperature subnormal. As I had no pilocarpine, and it was late on Sunday evening I administered a diuretic and diaphoretic mixture. My assistant continued to watch the case, administering chloroform occasionally when the fits were frequent and severe. On the 22nd I was called at 5.45 A.M. as the patient was in another fit. I administered chloroform, which quieted her, and this was kept up intermittently till 8.30 A.M. The fits began by a slight twitching of the left hand which gradually spread to the right side, when the head was drawn violently to the latter side, the teeth closing by clonic contraction of the jaw, biting the tongue at times and slightly drawing blood; the average duration of the fits was five minutes. Slight pressure on the carotids had an effect upon the duration of the fits, and as their intensity decreased the patient produced a peculiar suction noise with her nose as if in violent inspiration. The temperature was 102·5° and the pulse was 146. As the seizures were beginning to weaken the strength of the patient, as was evidenced by the rapid pulse-rate (160) and the high temperature (105°) at 10 A.M. I obtained some pilocarpine and gave her a hypodermic injection of one-fifth of a grain. Soon afterwards profuse diaphoresis set in and at 10.30 P.M. she had not had a fit since. I then drew off 20 ounces of urine, its specific gravity being 1016. The pulse was 136 and the temperature was 99·7°. The patient partook freely of milk and other liquid nourishment. The urine contained one-third per cent. of albumin. On the 25th on my visit I found her maniacal and fanciful, shuddering, and imagining that crawling beasts were about. The temperature was 99·4° and the pulse was 125. She remained maniacal for three days. On the evening of the 27th I gave her 15 grains of sulphonal which caused sleep for about eight hours. On the 28th she appeared to be much better. She was cheerful, but remembered nothing of what she had gone through. A specimen of urine drawn off and carefully examined was found to contain more para-globulin than serum-albumin, and after separation of the para-globulin there was a considerable reaction with nitric acid. From the 28th to Nov. 11th she made an uninterrupted recovery with the exception of a slight tendency to mania. On the latter date there was little reaction with nitric acid; it was scarcely observable with heat.

PATHOLOGY.

Owing to the small number of cases where a necropsy can be obtained on those patients who die the pathology is not well established. Some authorities have observed a dropsy of the ventricles of the brain which they assume causes pressure and nerve-irritation. Others have noticed an anæmic condition of the brain and nerve centres, while another authority is of opinion that the fits are due to thrombi and to the minute hæmorrhages which they have observed, which they assert are caused by the increased coagulability of the blood in pregnancy, but this is not proved by experience. Most authorities believe that the pathological state is to be found in the kidneys, Bright's disease causing faulty elimination of the waste products of tissue metabolism.

PROGNOSIS.

The death-rate in this disease is not quite so high as is generally believed. Authorities on the subject are very divergent, ranging from an abnormally low to an abnormally high rate. This may be due in some measure to partisanship, for men who adopt and advocate a certain line of treatment are apt to show off their own results in the most favourable light, while the results of men who adopt another treatment are less favourably commented on. Galabin gives the death-rate as being 30 per cent., but this I am certain is much too high—one-third of this rate I consider nearer the normal. To give a word of hope to the relatives of the patient in a grave complication of this kind is important, and if Herman's view is correct this can be done almost with certainty by systematic examination of the urine where possible. If the albumin is principally para globulin then with judicious treatment recovery may be predicted with safety, while if the convulsions are due to Bright's disease recovery would be a matter of some doubt.

TREATMENT.

We are apt in this disease as in all others to become empirical in our treatment. A certain line of treatment is very often discredited by the method in which it is employed and carried out, by a want of care and observation on the part of the practitioner in not selecting the proper treatment for the case in question. No special line of treatment is suitable for all cases, inasmuch as many cases of eclampsia will recover speedily with a simple diuretic and diaphoretic mixture and application of heat to the body by means of the hot air or vapour bath or by the simpler means of hot-water bags, but there are other cases in which this is quite inadequate to produce the desired effect—viz., the cessation of the convulsions. One must then adopt more powerful remedies for ridding the system of the effete matter and for allaying the irritability of the cerebro spinal system. Morphine has been much used of late and has produced good results with different authorities. Lyle[1] records one death in eight cases lately treated in this manner at the Rotunda, giving a death-rate of 12·5 per cent. Fitzgerald[2] records two cases treated with morphine and atropine with successful results. The results with this remedy have certainly proved encouraging. Morphine is a powerful anodyne in allaying the irritability of the cerebro spinal system and so controlling the convulsions, but even with this remedy there are cases where fatal results are likely to follow—e.g., cases of nephritis with renal inadequacy. It is taught in the text-books of materia medica that opium or its derivatives should not be given in Bright's disease, as it causes convulsions and death; it is possible that this teaching is just as true as it was 20 years ago notwithstanding the seeming contradiction in treating eclampsia with morphine. It has been asserted by Herman, and I think justly, that in the great majority of cases of eclampsia the albumin found in the urine is not due to nephritis, but to altered blood-pressure in the blood-vessels, and when this is so the patient after delivery rapidly recovers and it leaves no evil effects behind; but when the albumin is due to nephritis the condition is much more grave—the kidneys take a much longer time to recover, and the patient is more apt to die than those in the former category. It is just possible that the fatal case recorded by Lyle belonged to the latter class and that morphine is certain to cause fatal results in nephritic cases. It is important, therefore carefully to examine the urine quantitatively as well as qualitatively, and should the para globulin be in greater proportion than the serum-albumin, then it belongs to the class where altered pressure is the cause of the albuminuria, thus indicating in my judgment, whether or not morphine should be used. Pilocarpine is a powerful remedy but it is distrusted by some. In doses of one-fifth of a grain hypodermically it produces profuse diaphoresis in less than 20 minutes, and in my last case of post-partum eclampsia, after diuretics, diaphoretics, chloral bromide, and chloroform had all had a fair trial without in any way curing the convulsions, it acted in the most happy manner. The patient had no more convulsions after its administration, and none of the bad effects, such as profuse salivation, which, according to some, follow its use, occurred. Others have found pilocarpine to produce the same result. Inglis[3] records a case in which the convulsions ceased immediately after the subcutaneous injection of one-fifth of a grain. Recently treatment by infusion or transfusion of saline solution, either subcutaneously or intravenously, has been much practised and advocated. Jardine[4] records 22 cases treated in this manner with three deaths, equal to a death-rate of nearly 14 per cent. Intravenous transfusion I consider bad treatment even in cases of severe post-partum hæmorrhage, as saline solutions can be introduced into the circulation with safety by less dangerous methods—e.g., per rectum and subcutaneously. In all cases of eclampsia I should advocate the less heroic methods first, and if no good result be obtained then I should resort to the more powerful remedies, preferring pilocarpine to any other drug in suitable cases. I believe that the great dissimilarity in the methods which are adopted and the results which are obtained in the treatment of this complication of the puerperal state are due to the want of method in approaching the treatment of the disease. First of all, if the case permits of this investigation, we must ascertain whether the para-globulin or serum albumin is in the greater proportion. If we obtain this comparative analysis then the treatment is easy, but if the practitioner be unable to obtain this data then I should advocate the simpler methods—first, diuretics, diaphoretics, bromide, chloral, and chloroform—before resorting to morphine or hypodermoclysis, keeping in mind the safety of the patient above all other things, and the particular treatment as of secondary importance. If the eclampsia appears in the first months of pregnancy forcible measures in emptying the uterus should be avoided even under chloroform, as one never knows how much damage may be caused to the uterus by this means. Nature is, as a rule, gentle in her methods, therefore the bougie is more likely to act beneficially than is forcible emptying of the uterus. It should be kept *in situ* so long as to produce powerful and regular contractions, and then withdrawn, to be re-inserted if the pains lag. Venesection is a valuable form of treatment if the patient is plethoric, but to bleed indiscriminately is, in my judgment, bad treatment.

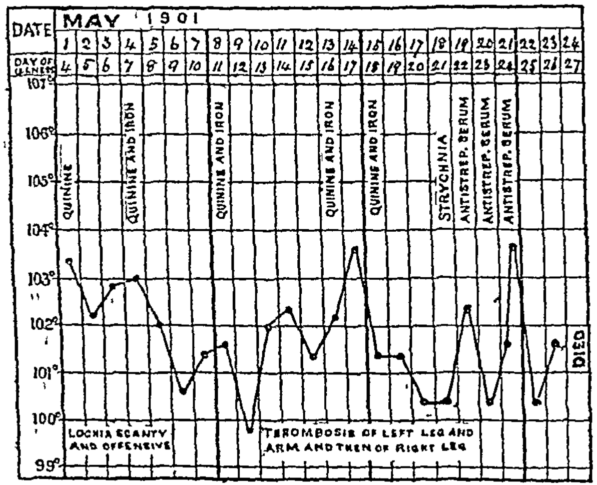
MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

A CASE OF PUERPERAL FEVER TREATED WITH ANTI-STREPTOCOCCIC SERUM; DEATH.

By F. W. Thurnam, M.B., C.M. Edin.

A married woman, aged 34 years, the mother of four children, and who had had three miscarriages, was safely delivered by me, after a normal labour, at 6 p.m. on April 27th, 1901. All appeared to be going on satisfactorily till the fourth day (May 1st) when her temperature, which had been 99°F. the previous day, was 103·4°, and the lochia were scanty and offensive. Quinine and uterine injections of 2 per cent. solution of creolin reduced the temperature one degree on the following day, but it rose again till on May 4th it was 103°. Doses of five grains of quinine with 20 minims of solution of perchloride of iron given every four hours brought it down to 100·4° on the 6th, and, after an intervening rise to 101·8°, to 99·8° on the 9th. After this date there was thrombosis of the left leg and subsequently of the arm on the same side and of the other leg. There was some thickening, probably perimetritis, mostly on the left side. There was diarrhœa from May 7th to 19th, which was checked to some extent by chalk mixture and benzo-naphthol with port wine. A troublesome crop of boils formed on the buttocks and one of them went on to a bedsore, after some incontinence of urine, which was albuminous. The rigors were numerous and there was more or less delirium, though the tongue remained clean throughout. The pulse and respiration did not correspond with the temperature. From facts which came to my knowledge the source of mischief pointed only too plainly to the nurse who was dismissed on May 4th. On the 14th the temperature was 103·6°, falling by the 17th to 100·4°. On the 19th it was 102·4°, when Dr. H. B. Carter saw the patient with me and we decided to try anti-streptococcic serum, which I procured from the Jenner Institute, and at 8 p.m. 20 cubic centimetres were injected, the temperature falling to 100·4° at noon on the 20th, when I injected 10 cubic centimetres. On the 21st the temperature was 101·6°, so at 11 p.m. I injected 30 cubic centimetres of serum. Half an hour afterwards the temperature was 103·6°, but on the next morning it was 100·4°, rising on the 23rd to 101·7°. The patient died at noon on May 24th. The respiration rose gradually from 20 to 60 per minute, latterly with moist râles. From the 18th strychnia and brandy were necessary.



Having been probably fortunate in this being the only case of puerperal fever which I have had to encounter in my own practice I desire to call attention to the rise of 2° after the injection on May 21st. I, however, cannot be certain that this was due to the anti-streptococcic serum, and consider that bleeding and the injection of saline solution would not have been of benefit under the circumstances and that the combination of iron and quinine was on the whole preferable.

New-cross, S.E.

A CASE OF PUNCTURED FRACTURE OF THE SKULL COMPLICATED WITH OTHER SEVERE INJURIES; RECOVERY.

By Edward A. Piggott, L.R.C.P. & S. Edin., L.S.A. Lond.

On August 30th, 1900, I was called by telegraph some nine miles from my residence to attend the subject of this note. The patient, a builder and contractor by occupation, aged 46 years, in the course of his duties had been unfortunate enough to fall down a deep well; but I cannot do better than quote the following account of the accident from the *Brick and Pottery Trades Journal*:—

"In August last Mr. J. was engaged in carrying out extensive works at the Manor, Cowlinge, Suffolk. He had employed an experienced well engineer to sink a new well for the water-supply, and being desirous of personally examining the work he requested the well foreman to let him down to the bottom. Unfortunately, Mr. J. went a good deal quicker than he anticipated, for a man employed on the surface to manage the tackle discovered when too late, that Mr. J. had got into the large bucket before everything was ready. It appeared that the man who had charge of the handle had not attached it to the roller in a proper manner, and Mr. J. was dropped no less a distance than 102 feet. His fall was broken by becoming impaled on the bore iron which happened to be still standing in the well. It spiked him through the thigh and held him there until assistance was forthcoming. He was taken to the top, where it was discovered that the thigh was torn open for a considerable distance, and his skull severely fractured."

The patient was removed to his residence from the scene of the accident as soon as practicable, and a careful examination made at 4 A.M. on the 31st revealed the following injuries. There was a wound of the scalp some two and a half inches square exposing the bone, situated a little posterior to the left parietal eminence and encroaching on the position of the lambdoid suture. There was no sign of depression or fissure of the external table of the skull, but in the centre of the wound there was a distinct puncture which penetrated the diploë. On the inner side of the right thigh, some three inches above the knee-joint, was a lacerated wound measuring four inches transversely and extending along the inner border of the rectus femoris, beneath the sartorius, and terminating deeply amongst the muscles in the neighbourhood of the apex of Scarpa's triangle; from this wound there was profuse venous hæmorrhage. Fortunately the femoral artery escaped injury. The right lumbar region, the right buttock, and the whole of the right thigh were one continuous track of ecchymosis—in fact, black with effused blood. The pelvic bones and femur were free from lesion.

The condition of the patient at 11 A.M. on August 31st was as follows. He was perfectly unconscious; his breathing was laboured and at times was inclined to be stertorous. The pupils were unequal, the pulse was 120, and the temperature was normal. As no urine had been passed since the accident on the previous afternoon a catheter was passed and the bladder was emptied. The head was shaved and an ice-bag was applied; small quantities of milk and soda-water and beef-tea were ordered to be given at intervals. The patient was placed upon a water-bed as soon as one could be procured. For the next few days he remained in a state of semi-consciousness, alternating with most violent attacks of delirium, requiring at times two men in addition to the nurses to control him. The catheter had to be employed night and morning until Sept. 5th, on which date the bladder resumed its normal action. On the evening of Sept. 7th the temperature suddenly rose to 100 8° F. The whole day the patient was more or less delirious, the symptoms indicating irritation of the brain; the next morning the temperature fell to the normal point, and during the remainder of the treatment never rose above 100 4°—the point attained on Oct. 4th and 6th, its usual range being from 97 4° to 99°. The pulse-rate was generally between 80 and 96; the hightest rate recorded was 120 on the evening of Sept. 7th. The respiration rate ranged between 20 and 24. The wound in the thigh was very tedious in its progress and necessitated a hypodermic injection of morphine (a quarter of a grain of bi-meconate) each night when dressed. A considerable amount of sloughing of integument and fascia was unavoidable; it eventually healed by granulation and was systematically dressed for the last time on Oct. 31st, the patient leaving home for the sea-coast on Nov. 6th.

Remarks—The case is remarkable, more especially as regards the depth of the fall. There were never any decided symptoms of compression, those of irritation being most marked. Abscess and the trephine I most dreaded, but the brain mischief gradually and steadily improved. Great credit was due to a man working on a platform at the bottom of the well at the time of the accident, who, although suffering from three fractured ribs and a laceration of the face caused by the falling gear, managed by means of the tackle to send his more severely-injured companion to the surface. I must express my indebtedness to Mr R H Wilkin of Wickhambrook who saw the patient with me immediately after the accident, and also to Mr. R. W. Waring of Cavendish, who met me several times in consultation.

Clare, Suffolk.

ASPARAGUS AND HÆMATURIA.

BY J. S. MACKINTOSH, M.R C.S. ENG., L.R C.P. LOND.

ON May 25th last an old gentleman, aged 73 years, sent to me a bottle of his urine, passed between 11 P.M. and 4 A.M. on the previous night, which had alarmed him by its dark colour. On testing it gave reactions for albumin and blood and under the microscope plenty of blood-corpuscles and a few blood-casts could be seen. This, together with the smoky colour of the urine, pointed clearly to the kidney itself as the source of the hæmorrhage. On calling to see the patient I found him busy in his study, looking and feeling quite well. The history he gave was that he was very fond of asparagus and that two days previously he had had a fine bundle sent to him from the country, which he had consumed at luncheon and dinner on each of the two days, taking at each meal "about as much as he could grasp with one hand." He owned an astronomical telescope, and after dinner on the second day (the evening before the hæmaturia took place) he went out to give a demonstration of the moon to some friends. The day had been warm, but the evening, with the strong east wind prevalent at that date, became very cold. The patient did not notice the cold until the end of the demonstration, when he felt that he had got chilled. About midnight he had a desire to urinate and he passed the urine of which he sent to me a specimen. In the evening he sent to me another specimen of the urine passed during the day after I had seen him. In this there was no trace whatever of albumin, blood, or casts. There has been no abnormality of the urine since. The patient had a prejudice against drugs, so, as there had been no symptoms whatever of an acute nephritis beyond the condition of the urine, he was recommended to confine his diet to slops and to keep himself under observation.

Asparagus is a stimulant diuretic causing dilatation of the afferent and contraction of the efferent blood-vessels of the kidney. The patient, then, with the kidneys engorged with blood exposed himself to a thorough cooling of the surface of the body. The mode of production of the hæmaturia seems plain enough. What is not so clear is its transient character. Apparently, a train had been well laid to lead to an explosion of an acute nephritis, but ended, happily, in a mere fizzle. The patient himself is, for his years, remarkably active, both in mind and body. Of spare habit and small stature he *enjoys, as a rule*, excellent health, beyond occasional slight "uricacidity" manifestations. He exhibits a degree of arterio-sclerosis not uncommon at his age, but of chronic interstitial nephritis no symptoms at all. The moral appears to be that exposure to a chill after indulgence in asparagus is not without its dangers.

BEDFORD COUNTY HOSPITAL.

A CASE OF PANCREATIC CYST OR EFFUSION INTO THE LESSER PERITONEAL CAVITY; DRAINAGE; *RECOVERY.*

(Under the care of Dr R. H. COOMBS and Mr. W. GIFFORD NASH.)

THE diagnosis between true cysts of the pancreas and effusions into the lesser peritoneal cavity is very difficult even after a laparotomy has been performed. In the following very interesting case the arguments certainly appear to be in favour of the cyst being an effusion into the small sac of the peritoneum, and much may be said on behalf of Mr. Gifford Nash's contention that the absence of a history of trauma is a fairly trustworthy criterion that a doubtful cystic swelling in this situation is a cyst of the pancreas rather than a peritoneal effusion.

A girl, aged four years, was admitted into the Bedford County Hospital on Feb. 3rd, 1900, under the care of Dr. R. H. Coombs. In the summer of 1899 she had whooping-cough and at the end of October began to suffer from attacks of abdominal pain and vomiting. These attacks continued and she lost flesh. An attack of abdominal pain on Feb. 1st was the cause of her being taken to the hospital. There was no obtainable history of any injury to the abdomen. On admission the abdomen was found to be slightly distended but not tender, and by some it was thought to contain a little free fluid. There was some resistance to be felt below the left costal margin. Mr. Gifford Nash saw the child a few days after admission and found some tenderness and deep resistance in the left epigastric and hypochondriac regions just below the edge of the ribs (Fig. 1). No

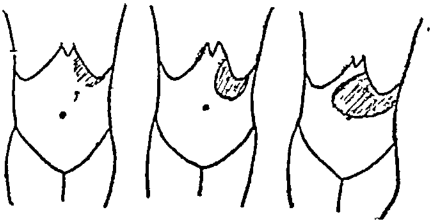

FIG. 1. FIG. 2. FIG. 3.

Fig 1, condition from Feb. 3rd to 12th. Fig. 2, condition on Feb. 13th Fig 3, condition on Feb. 20th. The shaded portion shows the extent of the tumour.

lump of any kind could be detected. The symptoms suggested trouble in the region of the pancreas, but no definite diagnosis could be made. During the night of Feb. 12th the child frequently complained of severe pain in the stomach, and next morning a tumour was seen and felt in the left epigastric and hypochondriac regions (Fig. 2). The tumour extended upwards under the ribs and downwards into the left loin. The margin was rounded and the tumour was elastic and fluctuating. It suggested from its situation, shape, and rapid appearance a hydronephrosis of the left kidney, but the presence of colon resonance behind it showed that it did not arise from this organ. It was also suggested that it was a splenic tumour, but its rapid appearance and cystic nature put this out of the question. Mr Nash concluded that it must be either a pancreatic cyst or an effusion into the lesser peritoneal cavity. During the next few days the tumour increased in size and became more tense and fixed. It passed across the middle line and extended upwards so as to be continuous with the area of liver dulness. It extended downwards to the umbilicus (Fig. 3). The stomach lay in front of the upper part of the swelling. Except that the appetite was poor and that there was some pain there were no gastric, intestinal, or urinary symptoms and no rise of temperature. Examination of the blood showed no change except a slight increase of leucocytes. A diagnosis of a pancreatic cyst having been made, it was determined to drain it by an anterior incision.

An operation was performed on Feb. 20th. An incision three inches long was made in the left linea semilunaris over the most prominent part of the tumour. The stomach was found flattened out over the anterior and upper part of a very tense cyst. The incision was prolonged downwards and the transverse colon was found crossing the lower part of the cyst A vertical incision was made in the gastro colic omentum which formed part of the wall of the cyst. After tearing through a layer of fatty tissue a white fibrous cyst was exposed resembling in appearance an ovarian cyst. A trocar was inserted and about 30 ounces of dark brown fluid were evacuated. This spurted out as if retained under considerable pressure. The edges of the cyst were stitched to the

edges of the peritoneum only and the wound was closed except where a drainage-tube was left in. The cyst wall was about one-eighth of an inch thick and was very vascular. Its interior felt velvety and looked deeply congested. A finger in the cyst felt the liver above, the spleen and left kidney to the left and behind, and at the back of the cyst the aorta and an irregular soft mass, presumably the pancreas. In the position of Winslow's foramen a small pocket could be felt but it was apparently closed.

The fluid in bulk was almost black, but in a test tube it appeared reddish-brown from the presence of blood. It was alkaline, highly albuminous, converted starch into sugar, and emulsified fats. It did not contain bile. The specific gravity was 1017. Under the microscope were seen numerous red blood corpuscles, some large granular cells which stained with methylene blue, and some tyrosin crystals.

After the operation there was a little discharge from the sinus of a clear fluid which irritated the skin to a slight extent. The sinus was kept open by a small tube or piece of gauze until the middle of May, when the tube was omitted for good. A week later the fistula was completely healed, having continued discharging for three months. The child was seen in December, 1900, in perfect health, and no trace of any swelling could be felt in the abdomen.

Remarks by MR. GIFFORD NASH.—There is no doubt that this cyst occupied the position of the lesser peritoneal cavity and that it communicated with some duct of the pancreas as shown by the nature of the fluid. Was the fluid in the lesser peritoneal sac or was it in a cyst of the pancreas which occupied the sac? I am inclined to think that it was an effusion into the lesser cavity of the peritoneum for the following reasons 1. The history of a sudden appearance of a fluid tumour in the left side of the abdomen. No cyst due to the dilatation of a duct could form in a single night. Senn has proved experimentally that sudden blockage of a pancreatic duct does not produce a retention cyst. The position of the swelling, too, was exactly in the situation of the lesser peritoneal cavity. 2. It might be expected that the contents of a cyst due to a dilated pancreatic duct would be clear, somewhat like the fluid contained in a ranula, but here the fluid was highly albuminous and contained much blood—in fact, it was such a fluid as one would expect to be poured out by a highly-congested peritoneum when stimulated by the presence of an irritating fluid. 3 The quantity of fluid which was poured out in a single night must have been quite a pint. After the cyst was opened and the irritation was removed the quantity discharged daily was but a few teaspoonfuls and in character clear and glairy.

My explanation of the case is as follows. The attack of whooping-cough in 1899 caused some injury or an effusion of blood into the pancreas. This gave rise to the occasional attacks of pain and vomiting and to the deep epigastric resistance. Possibly a small cyst formed in the pancreas at the seat of injury. The manipulations of several persons attempting to diagnose the case between Feb. 3rd and 12th ruptured the cyst and produced some extravasation of pancreatic fluid into the lesser peritoneal sac, and this set up a profuse hæmorrhagic effusion.

Until 1892 this case would undoubtedly have been considered to be a pancreatic cyst, but in that year Mr. Jordan Lloyd[1] published a paper on Two Cases of Effusion into the Lesser Peritoneal Cavity, and since that date many similar cases have been reported. Mr. Jordan Lloyd pointed out that the tumour caused by effusion into the lesser peritoneal cavity lies in the left hypochondriac, epigastric, and umbilical regions, and that the stomach lies above and the colon below it. The conclusions he came to may be summed up as follows: (1) that contusions of the upper part of the abdomen may be followed by the development of a tumour in the epigastric, umbilical, or left hypochondriac regions; (2) that such tumours may be due to a fluid accumulation in the lesser peritoneal cavity; (3) that when the contents of such tumours are found to have the property of rapidly converting starch into sugar it may be assumed that the pancreas has been injured; and (4) that many such tumours have been regarded as true retention cysts of the pancreas, and that this opinion has been formed on insufficient evidence.

The first paper on cysts of the pancreas was published by Senn in the *American Journal of the Medical Sciences* in July, 1885. Several of the cases collected by him had been operated on as ovarian cysts and the attempts at removal had almost invariably proved fatal. With regard to these cysts of the pancreas Senn stated that—"(*a*) All cases have occurred in adults; (*b*) sex has no influence; and (*c*) traumatism is a frequent exciting cause."

Subsequent experience has shown that the first two of these statements require modification. "(*a*) All cases have occurred in adults." This is no longer true, as out of 54 cases which I have collected 12 have occurred under the age of 20 years, one patient being aged two years and another four years. Out of 25 traumatic cases nine have been under 20 years of age. "(*b*) Sex has no influence." This is not so, as out of 25 cases in which there was a clear history of injury 23 were males and only two were females. On the other hand, out of 29 cases in which there was no history of injury 18 were females and 11 were males. It has occurred to me that tight-lacing may have some influence in producing the preponderance in females. "(*c*) Traumatism is a frequent exciting cause." If it is considered that every case in which a cystic collection of fluid occurs giving the reactions of pancreatic juice is a cyst of the pancreas, then this statement is true, but if these cases are divided into true pancreatic cysts and effusions into the lesser peritoneal cavity containing pancreatic fluid then I would say that traumatism is a frequent cause of the latter, but, as far as is known, not of the former.

Senn also pointed out that the rapid growth of the tumour is in favour of pancreatic origin, that pain is not a constant symptom, and that there are no serious symptoms apart from pressure on the surrounding structures. He gave nine affections from which these cases must be diagnosed—viz., (1) malignant disease of the pancreas or adjacent organs; (2) aneurysm; (3) hydatid cyst; (4) affections of the retroperitoneal glands; (5) hydro- or pyo-nephrosis; (6) cyst of the suprarenal body; (7) circumscribed peritonitis or exudation; (8) ascites; and (9) cystic disease of the ovary. To these, I think, might be added distension of the gall-bladder.

I have collected 54 cases of pancreatic cyst or effusion into the lesser peritoneal cavity and have classified them as traumatic and non-traumatic. The traumatic cases number 25 (Table I.) and the non-traumatic 29 (Table II.). Of the traumatic cases 23 were males and two were females, and of the non-traumatic cases 11 were males and 18 were females. The average age of the patients in the traumatic cases was 25 years and that of the non-traumatic 36½ years. The age of the youngest patient in the traumatic cases was two years and that of the non-traumatic cases was four years. In most cases due to injury a cyst requiring operation was produced in a few weeks, but the non-traumatic cases usually gave a long history, often of many years' duration, and in some of these it is possible that there may have been an injury which had been forgotten. Patients in whom there was no history of injury generally gave a history of attacks of pain, occasionally very severe, in the epigastrium (so-called cœliac neuralgia), followed eventually by an acute attack of pain and sickness and formation of a swelling. This sudden attack probably announced the rupture of a cyst into the lesser peritoneal cavity. The nature of the injuries causing these effusions has been falls, blows, or crushes.

Some of the earliest cases recorded were treated by attempts at enucleation, but this method proved almost invariably fatal. Complete removal is impossible except in the case of a small cyst of the pancreas, such as that operated on by Clutton, in which the cyst sprang from the tail of the pancreas. Aspiration has been adopted many times, but in some instances it has proved fatal and in many it has been followed by recurrence of the tumour. Lynn Thomas treated a traumatic cyst in a child, aged two years, by aspiration with complete success. It is, however, generally agreed that aspiration is dangerous, even as a means of diagnosis, as it is almost impossible to avoid penetrating the stomach which is stretched out over the front of the tumour, and as a means of treatment it is generally useless. The acknowledged operation is incision and drainage, which is most easily done by an anterior opening. The cyst is opened between the stomach and the transverse colon. It is probable, however, that a posterior incision below the last rib on the left side will give the best result and this method has been adopted in a few instances. The fistula generally heals in less than four months, but may heal even after two years' duration. In one case at least it has remained permanently and in another (Gould's case) it was followed by a malignant growth which proved fatal. In Jacobson's case the cyst refilled a year after treatment by incision and drainage. The risk of operation by incision and drainage appears to be very slight.

ROMAN CATHOLIC SANATORIUM, PIETERMARITZBURG.

A CASE OF NEPHRO-LITHOTOMY IN WHICH THE DIAGNOSIS OF RENAL CALCULUS WAS CONFIRMED BY THE X RAYS.

(Under the care of Dr. C. J. CURRIE.)

THE difficulties of obtaining a skiagram of a renal calculus are great, partly because of the large amount of soft tissues through which the rays have to pass and partly because of the blurring of the shadow owing to respiratory movements. There is, however, a third cause which is probably as important as either of the others—namely, the nature of the stone. The best shadow is given with a calculus composed of oxalate of lime, but a uric acid calculus or one consisting of phosphates gives a much less distinct shadow on the sensitive plate. In the case reported below the fact that the urine was alkaline and contained crystals of triple phosphates renders it almost certain that this dendritic renal calculus was in great part phosphatic, with not improbably a nucleus of uric acid; this may serve to account for the difficulty in obtaining a good skiagram.

A European, aged 40 years, first came under Dr. Currie's care in January, 1901, complaining of pain in the right loin. The patient stated that he had passed mucus and pus in the urine for 15 or 20 years, but that the pain in the loin was not very severe till about three months before, and that he had had it off and on ever since. The urine contained pus, mucus, and albumin, but no blood, and under the microscope crystals of triple phosphates were observed. The urine was alkaline and of specific gravity 1018. The patient was treated first with citrate of potash and then with piperazine, but as after a month's treatment no improvement was noted he was admitted to the Roman Catholic Sanatorium. On Feb. 20th he was radiographed by Mr. A. Allerston, and the plate on being intensified showed faintly but distinctly evidence of a stone in the kidney.

On Feb. 25th Dr. Currie, assisted by Mr. Ward, Dr. Buntine, and Dr. Taylor, cut down on the kidney by the usual lumbar incision, which was afterwards increased by a small vertical incision to give more room, and removed a large branched phosphatic calculus from the pelvis and calices of the kidney. The stone broke on being grasped by the forceps and was extracted in four pieces, which together weighed 200 grains. Hæmorrhage from the renal tissue was free and a drainage tube and plug of iodoform gauze were placed in the kidney wound. The incisions in the lumbar fascia and muscles were sewn up with a continuous catgut suture and the skin and fat were brought together with interrupted silkworm-gut sutures. The plug, which caused considerable pain, was after 24 hours removed under chloroform, and the tube was gradually shortened The wound ran an aseptic course and healed by first intention, except where the tube and gauze strip came through, and the patient made an uneventful recovery. On March 29th he still had a urinary fistula, but it was closing rapidly.

Since the above was written the patient was seized with pain in the prostatic urethra followed by an attack of orchitis. He thinks he passed some gravel, but unfortunately the urine supposed to contain it was thrown away without being carefully examined. The orchitis is now subsiding (April 6th) and the fistula is nearly closed.

Remarks by Mr. A. ALLERSTON.—The first time that I tried to take a radiograph of a renal calculus was some three or four years ago, but the apparatus that I was using then only gave a six-inch spark and the experiment failed During the recent Boer war I have been in charge of the x-ray apparatus belonging to the Natal Volunteer Department. This apparatus, which I used in the present case, gives a 12-inch spark and was manufactured by Apps I used a Crookes's tube with an osmium anode. The tube was distant from the plate 18 inches; one picture was made and an exposure of 20 minutes was given.

The thorax and upper part of the abdomen were bandaged to restrain the respiratory movements as much as possible and the exposure was intermittent, lasting 30 seconds at a time, with regular intervals of 30 seconds, the patient being directed to hold his breath during the exposure. By this means the blurring of the negative due to the upward and downward movements of the kidney during respiration was obviated. When the plate was developed I could see four distinct shadows which I then thought were four stones, being confident that as the other parts of the plate were clear these shadows must have been caused by some obstruction to the rays. I intensified the plate with mercury which showed up the shadows more distinctly, but I could not manage to get off a print.

A few days afterwards nephro-lithotomy was performed and a stone weighing 200 grains was removed. The stone, which had four branches, was as near as possible of the size of the shadow on the plate. I have had several cases since and I have detected a stone in one.

Medical Societies.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Case.—Double Hernia with Unusual Complications.—Appendicitis with Unusual Complications.—Anomalous Cerebral Cases.—Perforating Dysenteric Ulcer of the Colon.—Empyema.

A MEETING of this society was held on June 18th, Mr. P. E. MIALL being in the chair.

Dr. J. KERR showed a patient operated on for Mastoid Disease.

Mr. W. H. HORROCKS read notes on a case of Double Hernia with Unusual Complications. The patient was a male child, nine and a half months old, who had a double inguinal hernia and also a spina bifida. On the left side the sac was tense and there was no impulse on crying. The skin of the part was red and œdematous. The right hernia was irreducible and the external ring was very large. The bowels were acting. On opening the sac in the left side a few drops of pus escaped and a narrow band, ulcerated at its extremity, was found leading up through the ring to the small intestine; this turned out to be a Meckel's diverticulum. It was removed and the stump inverted. The sac and testicle being infiltrated with pus were removed together and the ring closed with catgut sutures. The wound healed well. A fortnight later the hernia on the right side was operated on. The sac was found to contain the lower part of the cæcum which was free; the posterior and inner aspects of the latter were devoid of peritoneal investment. The testicle was in its natural position. The bowel was gently reduced without interfering with its vascular supply and the peritoneum closed and the ring sutured. The wound healed well.

Dr. C. F. ALTHORP described a case of Appendicitis with Unusual Complications, and showed the vermiform appendix containing a concretion, and also a small ovarian tumour removed from the same patient. The patient was a woman, aged 22 years, who during two years had six attacks of appendicitis. On July 4th, 1900, the appendix, which was found to be fixed in the pelvis and matted by dense adhesions to the right ovary, was removed. The patient recovered from the operation, but was not relieved of her symptoms. A tumour was discovered in the position of the right broad ligament, and the abdomen was opened on May 8th, 1901. A fluid tumour of the size of a small orange was shelled out from between the layers of the broad ligament. The patient made a good recovery and went home well Dr. Althorp remarked that the right ovarian artery gave a branch to the appendix and also that the lymphatics of the two organs were somewhat intimately connected, and suggested that this connexion might account for the simultaneous occurrence of disease in the right ovary and the appendix.

Mr. R. MERCER read notes on three Anomalous Cerebral Cases. The first case was that of a woman, aged 25 years, who was suddenly (October, 1900) seized with giddiness, headache, and vomiting; these passed off and in two days she was back at work again. She remained at work a fortnight and then suddenly became unconscious and had an epileptiform attack. The fits recurred from every half hour to an hour and did not cease for 24 hours after the onset. She vomited from time to time and passed urine unconsciously. The urine contained a trace of albumin. There was no evidence of muscular weakness. The optic discs were normal. The pulse was slow and full, from 50 to 60 per minute. The temperature was slightly above normal. The respirations were stertorous. It was three weeks before she regained full consciousness. During this time she objected to the light, and after she began to talk again said that things were upside down. Examination of the field of vision showed left nasal hemianopia The pupils reacted normally. The patient was now (June, 1901) in excellent health and seemed to have no recollection of her illness previously to the complete return of consciousness. While the patient was in such a grave condition a diagnosis of tumour of the occipital lobe was made, but the subsequent recovery of the patient would seem to negative this. The second case was that of a woman, aged 32 years. She was emaciated, anæmic, and the subject of mitral incompetence and bronchitis. On April 28th she returned home from work feeling dizzy, she vomited frequently, and towards night became unconscious. She resisted attempts at examination and rolled about the bed. Her temperature was 103° F. and her pulse was 120. The tongue was dry and coated. The eyes were kept closed and the limbs were rigid. Urine and fæces were passed involuntarily. She vomited during the next day and remained unconscious for four days. Double optic neuritis was present. There was no albumin or sugar in the urine. There was noticed to be pigmentation of the skin and of the mucous membrane of the mouth. This, combined with the great prostration, would justify a diagnosis of Addison's disease, possibly associated with tuberculous deposit in the brain. The patient had a second attack of coma in which she died. There was no post-mortem examination. The third case was that of a woman, aged 53 years. She complained on July 10th, 1896, of severe pain at the back of the head. She was distressed and her manner was altered. There was no vomiting or optic neuritis. After a week she began to have a staggering gait and moved about with her eyes half shut Her memory failed and she neglected her dress and person. She became somnolent and took to her bed. Towards the end of August slight weakness of the right hand was observed and optic neuritis was detected. A diagnosis of cerebral tumour in the left arm centre was made. The skull was trephined on Sept. 10th over the left Rolandic area. The brain bulged, but no tumour was found. A trocar was inserted into the lateral ventricle and a quantity of fluid was evacuated. The patient died 12 hours after the operation. At the post-mortem examination a tumour of the size of a walnut was found in the left frontal lobe. The tumour was a glioma and was not multiple. An erroneous diagnosis as to the position of the tumour was founded on the paresis of the right hand. Similar cases had been described by Bruns and Ferrier.

Mr. J Phillips read notes on a case of Perforating Dysenteric Ulcer of the Colon with complications. A woman, aged 32 years, was admitted to the Bradford Royal Infirmary under the care of Mr. Althorp with sinuses in the right loin. There was a history of influenza twelve months before, followed by "inflammation of bowels" eight months before; the latter illness caused her to keep her bed for two or three months and was followed by right-sided pleurisy. Two months later a lump formed in the right loin which was opened and had discharged ever since. The largest of three sinuses in the loin admitted the finger, which passed up under the diaphragm. The chest was normal. The urine was normal. On April 24th the sinuses were scraped and a quantity of foul granulations removed. The sinus passed upwards and to the right beyond the reach of the finger. Two days later, on removing the packing, egg and milk came from the wound. A duodenal perforation was diagnosed and an anterior gastro enterostomy was performed, but the patient died from pneumonia two days later. At the necropsy, on removing the colon pus was found burrowing up behind the ascending colon to the subphrenic cavity, which was bounded above by the diaphragm, below and in front by the liver, and on the inner side by the kidney and duodenum; in the latter was an aperture admitting two fingers. The diaphragm was perforated and the lower lobe of the right lung was in a condition of septic pneumonia. The retro colic pus was due to perforation of two small ulcers just above the cæcum. The case appeared to be one of dysentery with perforation of a colic ulcer. followed by right subphrenic abscess, and eventually by perforation of the abscess through the diaphragm and duodenum.

Dr. Baxter-Tyrie read notes on some cases of Empyema.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Exhibition of Specimens.—The Digestive Power of the Peritoneum.—Concealed Accidental Hæmorrhage.—Bacteriological Diagnosis of Puerperal Infection.

A meeting of this society was held at Leeds on May 17th, Dr. T B Grimsdale, the President, being in the chair.

Dr. Lloyd Roberts (Manchester) showed: (1) Multiple Fibro-myoma, the largest growth being intra-ligamentary; the latter was enucleated from the broad ligament and the uterus was removed by supra-vaginal hysterectomy; and (2) a large Fibro myoma of the Fundus removed by abdominal myomectomy, the uterine bed being sutured with silk.

Mr. Walter Thompson (Leeds) showed: (1) Fibro-myoma Enucleated from the Broad Ligament; and (2) Large Spindle-celled Sarcomatous Uterus weighing 12¼ pounds, removed by total abdominal hysterectomy.

Dr. J. Braithwaite (Leeds) showed three Fibroids removed by abdominal myomectomy. In Case 1 the uterine cavity was opened; in Case 2 and Case 3 the cavity did not require opening. Reference was made to two other similar specimens not shown.

Dr. E. O. Croft (Leeds) showed a Complete recent Tubal Abortion. The abdomen was opened and found to be full of blood in which a perfect ovum of about six weeks' development was discovered. The Fallopian tube was unruptured, but its outer end was dilated into a cavity and the fimbriated opening was gaping widely.

Dr. J. B. Hellier (Leeds) showed: (1) Hæmatoma (Ectopic Gestation) removed from the Broad Ligament by Colpotomy (chorionic villi were present); (2) Tubo-uterine Gestation removed by Supra-vaginal Hysterectomy; and (3) Uterus removed for Carcinoma of the Cervix from a patient who had passed a Hydatidiform Mole three months previously.

Dr. Braithwaite (Leeds) read a paper on the Digestive Power of the Peritoneum. Cases were described in which the evidence seemed to point conclusively to the possibility of the absorption of extra uterine gestation products, not only in the early stages, but at full term.

Dr. A. E. L. Wear (Leeds) read a paper on a case of Concealed Accidental Hæmorrhage in which death occurred suddenly from syncope two hours after the uterus had been emptied and all bleeding stopped.

Dr. Arnold W. W. Lea (Manchester) read a paper on the Bacteriological Diagnosis of Puerperal Infection: its Value and Limitations. A more accurate knowledge of the bacterial invasion of puerperal infection was essential if further progress was to be made in the treatment. The uterine lochia from cases running a normal course were in the early days of the puerperium free from bacteria, though after the sixth or eighth day organisms were often present. In cases of suspected puerperal infection some of the uterine lochia might be obtained free from contamination with the vaginal discharge. The technique was briefly as follows. The patient was placed on her side and a duck bill speculum was passed; the vagina and cervix were cleansed with cotton wool. A sterilised glass tube was now introduced into the uterus and suction was made by a syringe. The tube was removed, the ends were sealed, and its contents were taken away for examination. 18 cases of puerperal infection were examined bacteriologically by this method. Cultures of the lochia were made on agar and gelatin tubes and in some of the cases anaerobic cultures were also made. The blood was examined in 14 cases. The results of these observations were as follows. Streptococcic infection was found in 10 cases. In six cases the streptococci were in pure culture, in two cases associated with streptococcus pyogenes aureus and albus, and in two cases with anaerobic bacteria. Of these, three recovered and seven ended fatally. Many of these cases were seen in the late stages of the disease and were of a very severe type. In one case vaginal hysterectomy was performed and the patient died from septic peritonitis which was not checked by the free drainage of the pelvis established by the operation. In nine cases of streptococcic infection cultures of the blood were made on agar tubes. In seven the blood was sterile. even in the later stages. In two cases streptococci were found in the blood. Both these patients died. With regard to staphylococcic infection these organisms were found in five cases. In two cases they were associated with streptococci; in two cases the staphylococcus pyogenes albus and aureus were in pure culture; and in one case they were associated with gas-producing anaerobic bacteria. Three of these cases died and two recovered. Bacterium coli commune was found in one case associated with anaerobic bacteria. As to anaerobic bacteria, these were not investigated in every case, but in five cases they were found to be present. The gas-producing bacillus was found in one case associated with putrefactive changes in the uterus. This case ended fatally. In three cases, although the symptoms pointed to severe puerperal infection, the uterine lochia were found to be sterile. In one the perineal laceration was infected with streptococci but the uterine cavity was sterile. All recovered rapidly. A detailed analysis of these cases was given in the paper. Streptococcic infection was by far the most common form of puerperal infection and presented enormous differences in virulence. In some cases the organisms caused few or no symptoms, remaining limited to the surface of the decidua or placental site. In other cases they rapidly invaded the uterine wall either by the lymphatic vessels—the so-called lymphatic form of septicæmia—or through the veins—the thrombo-phlebitic type; of these, the former appeared to be the most usual course. The extraordinary differences in the results of streptococcic invasion must be attributed to variations (1) in the virulence and type of the organism, and (2) in the resisting power of the individual. Of these factors they did not possess certain knowledge, and as yet bacteriology afforded little help. The gravity of cases must be judged mainly from the clinical symptoms. Diagnosis.—1. If the uterine lochia were sterile, microscopically and to culture, infection was eliminated. The gonococcus, however, might be present; it could be recognised by the microscope and staining. 2. If anaerobic bacteria only could be obtained decomposition was going on in utero. It was a case of sapræmic intoxication. It was possible, however, that at times these anaerobic bacteria might cause severe or even fatal infection. 3. If streptococcus pyogenes was found the case was one of streptococcic infection, but severity of the invasion must be estimated by the clinical signs. 4. If the streptococcus was present with staphylococcus pyogenes aureus or albus the case might be one of "mixed infection," but it was probable that the streptococcus was the infecting organism. 5. If a growth of aerobic bacilli was found there might be bacterium coli commune or certain putrefactive bacteria which caused putrid endometritis. In pure streptococcic infection there was no offensive odour of the lochia, which might be very scanty or in some cases abundant and sanious. The treatment of puerperal infection must be mainly directed by the clinical symptoms, but bacteriological examination was of value. If the uterine lochia were sterile no intra-uterine treatment was required. If the streptococcus was present an attempt should be made to disinfect the uterus by curettage and other local measures. In some cases of streptococcic infection which resisted milder measures hysterectomy might save life, but bacteriology as yet afforded little help in laying down indications for this operation. If bacteria of putrefaction were present exploration of the uterus and removal of decomposing products were essential. The anti-streptococcic serum should be given in cases of streptococcic infection, but a large series of cases bacteriologically examined was essential before a true estimate of the value of this treatment could be made. Serum was given in three cases of proved streptococcic infection. In two cases, though repeated injections were given, no effect was produced and the patients died. In one case the serum had apparently a favourable influence.

EDINBURGH OBSTETRICAL SOCIETY.

Exhibition of Specimens.—Eclampsia and the Thyroid Gland.

A MEETING of this society was held on June 12th, Dr. R. MILNE MURRAY, the President, being in the chair.

The following specimens were shown:—

Dr. D. BERRY HART: 1. A Fibroid Tumour removed by Pan-hysterectomy for symptoms due to pressure and metrorrhagia. 2. An Incomplete Tubal Abortion in which the gestation sac, measuring two inches by one and a half inches, was partly adherent to the fimbriated portion of the tube and half projected beyond the tubal end. The amniotic sac was well seen and the sac wall, averaging from one-half to seven-eighths of an inch in thickness, showed a good deal of blood extravasation. 3. A Parovarian Tumour with markedly twisted pedicle. 4. A Ruptured Ovarian Cyst from a girl, aged 14 years. 5. A large Papillomatous Cyst. 6. An Ovarian Tumour with Myxomatous and Cystic Parts, the latter lined with columnar epithelium.

Dr. R. C. BUIST (Dundee): A Uterus removed for Deciduoma Malignum after Hydatid Mole, with Microscopical Section.

Dr. J. HAIG FERGUSON: A Myomatous Uterus removed by Abdominal Hysterectomy.

Professor A. R. SIMPSON: 1. Labia Minora and Clitoris removed for Epithelioma from a patient, aged 32 years. 2. A bronze copy of the Porro Medal.

Dr. S. MACVIE: Sketches of Varicose Veins in a woman five months pregnant.

Dr. H. OLIPHANT NICHOLSON read a paper on Eclampsia and the Thyroid Gland. The blood during pregnancy increased in volume with a deficiency of the solid constituents of the serum leading to a lower specific gravity. The red blood corpuscles and albumin were relatively diminished while the number of white corpuscles was increased. This was one of the first blood changes which followed thyroidectomy. Other changes occurred in the blood during pregnancy: there was always a toxæmia as a result of fœtal metabolism, and as the fœtus grew the maternal blood would suffer to a greater extent as the amount of fœtal excretion would be larger. Towards the end of pregnancy the margin of safety to the mother was greatly contracted. Unsuitable diet, chiefly of the proteid class, or a sudden chill, or a variety of other circumstances might be sufficient to derange the mechanism and precipitate the symptoms of eclampsia. In pregnancy also there was a hypertrophy of the cardiac muscle and of the muscular coat of the blood-vessels, giving rise to increased vascular tension. It had been suggested that these conditions were dependent upon the toxic condition of the blood. The toxic theory of eclampsia was now the one generally held by most obstetricians and in this connexion the following points might be mentioned. 1. That in every case of pregnancy more or less toxæmia existed and that the blood intoxication became more profound towards the end of gestation. 2. That although the eclamptic state was due to a toxæmia, the toxic agent which excited the convulsions was probably not always the same—there seemed to be different types of the disease. 3. That the toxins might be produced in greater abundance in some cases (twin pregnancies) and that they were generally more virulent in primiparæ than in multiparæ. In the primipara mechanical pressure on the renal vessels might possibly come more into play, while in the multipara a certain degree of immunity against the toxin might have been acquired from previous pregnancies (Allbutt). 4. That in spite of very grave toxæmia no alarming symptoms would occur so long as elimination by the kidneys was sufficiently active. Of the nature of the toxins they knew nothing and there was no clear evidence to show where they were formed. There was some reason to believe that the fœtus played an important part in their production, because after its death the various symptoms usually abated. If the fœtus contributed a part of the poison, then it was unlikely that they could exert any control over its formation, so their efforts in the avoidance of eclampsia might be more usefully directed towards the maintenance of efficient renal function. A checking of elimination by the kidney, more or less suddenly produced, would result in the development of all the symptoms of eclampsia. Therefore the whole question of treatment, prophylactic and otherwise, turned upon elucidating the cause of this renal arrest. What was it that, during the course of the normal elimination of the toxins, suddenly threw the kidney out of gear? Lange noted that out of 25 pregnancies in which the usual hypertrophy of the thyroid did not occur albuminuria occurred in 20. Large doses of thyroidin were administered to pregnant women in whom the physiological enlargement of the gland had occurred and a marked diminution in the size of the gland resulted. One might therefore conclude that the normal hypertrophy of the thyroid gland in pregnancy was the result of a demand for extra secretion to meet the wants of increased metabolism. With a continuous supply of artificial secretion the gland was relieved of the additional strain and resumed its former size. Hallion observed similar effects, and Murray had on this hypothesis used thyroid extract in certain cases of goitre with marked success. Lange also gave thyroidin to a case where there was a pathological enlargement of the thyroid gland during pregnancy. A diminution in size again resulted. He stated that the exhibition of large doses of thyroidin to the mother were not contra-indicated and that no atrophying effects on the fœtus were noticed. In patients suffering from the nephritis of pregnancy thyroidin had distinct diuretic effects. Dr. Nicholson then gave the history of a woman pregnant for the third time; she had suffered from fits at her two previous labours. At the sixth month her urine was normal; a month afterwards it was albuminous and she complained of frontal headache, giddiness, dimness of vision, and her whole body was œdematous and puffy. She was put on a milk diet, confined to bed, and given a diuretic mixture. In the eighth month she had a fit which was treated with bromidia and chloral. The urine was scanty and solid with albumin on boiling. Sphygmographic tracings were taken of both radial arteries and these showed a contracted vessel and a pulse of high tension. The next day thyroid tabloids were begun, at first two and afterwards three a day. In three weeks she was able to engage in household work, the urine was normal in quantity and contained no albumin, and her other symptoms had almost disappeared. 12 days later she gave birth to a full-sized living child; the labour was accomplished without any untoward symptom and her recovery was uneventful. The albuminuria did not return. The œdema in this case was general and not of the kind seen in ordinary dropsy; it was of a much more solid character and only pitted on firm and prolonged pressure. Its character suggested that it was really of a myxœdematous nature. The albuminuria was probably of toxic origin. This might only lead to increased arterial tension, but in greater quantity it would, in addition, produce albuminuria. If the quantity of urine became diminished then the pre-eclamptic symptoms of headache, dimness of vision, &c., would appear; and the next stage was eclampsia. Free diuresis might prevent the development of symptoms. Diminution of urine at the end of pregnancy might be a most important danger signal. Albuminuria and œdema were not always present. High arterial tension, unless accompanied with free diuresis, should be taken as a warning of possible trouble. Symptoms such as these might be and were produced by defective action of the thyroid gland. Iodothyrin increased the excretion of urea and also the metabolic processes of the body. Thyroid extract had a distinct diuretic effect in diseases of the kidney, although apparently negative in healthy persons. It also lowered the blood-pressure and dilated the arteries. The internal secretion of the suprarenal bodies acted in an antagonistic manner, and one might assume that the balance between the two resulted in a certain arterial tone. If the thyroid secretion should become diminished the suprarenal influence on the arterioles, including those of the kidney, would be very profound. As regards treatment in the early stages, when there were increased tension of pulse and diminution of urine thyroid extract should be given twice or thrice daily, and proteid foods should be entirely forbidden at first. Iodide of potassium in small doses had been regarded as a specific for puerperal albuminuria; the iodine had been proved to be picked out by the thyroid gland and might be elaborated into the active iodothyrin. It had been suggested to give infusions with iodide of potassium instead of ordinary saline infusions in cases of eclampsia. If convulsions had already occurred then the use of thyroidin by the mouth would not be rapid enough. Liquor thyroidii, or, better still, fresh thyroid juice, in from 10 to 15 minims, should be given by hypodermic injection and repeated every hour or two if not followed by signs of improvement. For the immediate treatment of the convulsion morphia was the best remedy. It inhibited the various processes of metabolism, and this gave opportunity to the thyroid gland to recover itself. The dose should be large—not less than half a grain for the first injection. Eclamptic patients resisted the dangerous effects of the drug in a remarkable way. One grain and one and a half grains had been employed with uniformly good results. Morphia relieved the spasm of the arteries and diminished blood-pressure. Jardine and others had extolled the use of saline infusions. Probably one of the early effects was to relax arterial spasm and then diuresis would follow.—The President, Dr. C. E. Underhill, Dr. Berry Hart, Dr. William Russell, Dr. F. W. N. Haultain, Dr. J. W. Ballantyne, Dr. Macvie, Dr. James Ritchie, and Dr. William Fordyce discussed the paper, and Dr. Nicholson replied.

Plaistow and Canning Town Medical Society.—A meeting of this society was held at the Public Hall, Barking-road, E., on June 6th, Dr. W. C. Taylor being in the chair, and there was a good attendance.—After a short discussion of some medico-ethical subjects, having a purely local interest, Mr. Percy Rose showed a case of Lichen Planus in a young man and a case of Non-parasitic Sycosis in a middle-aged man.—Dr. J. Biernacki read a paper on the Diagnosis and Treatment of Typhoid Fever, a subject of special interest to the meeting owing to the epidemic prevailing in the district. He laid stress on the fact that, apart from Widal's reaction—a test not always easily available in private practice—there was no royal road to the diagnosis of the disease. In those cases in which continued fever was the only prominent symptom the special difficulty of diagnosis was dwelt upon. The symptoms having diagnostic significance were then considered *seriatim* and their relative values were weighed. With regard to the temperature a rapid rise to about the maximum was stated to be the rule. As regards enlargement of the spleen it was pointed out that the organ was in some cases almost diffluent and it offered very slight resistance to the hand on palpation. Diarrhœa had become of recent years comparatively rare, this characteristic almost amounting to a change in type. Dealing with the question of treatment Dr. Biernacki strongly advocated the routine use of Yeo's chlorine solution as against other intestinal antiseptics, including salol. For severe hæmorrhage, a full dose of morphia given hypodermically was recommended, and for oozing frequently-repeated doses of pure turpentine. He was not in favour of a liberal diet, as now often prescribed. Generally speaking, he used milk lightly skimmed, with an ounce of lactose added to each pint. Peptonised milk given for sickness was very apt to cause diarrhœa, and the same remark applied to strychnine—the most reliable drug in heart failure. For diarrhœa lead and opium pill was stated to be a generally reliable remedy. In the later stage of heart failure alcohol by the mouth should be given in addition to strychnine hypodermically. Digitalis was regarded as at the best of doubtful value and as being often dangerous, especially when the urine was scanty. In cases with high temperature the usual hydropathic methods were advocated, with the continuous pack in lieu of the bath in private practice. Quinine, it was maintained, should be reserved for critically high temperatures, so as to prevent a loss of effect owing to partial toleration. Phenacetin was very valuable in cases of insomnia with restlessness, but sulphonal was dangerous, especially when the typhoid condition was marked.—A brief discussion followed, and the proceedings terminated with a hearty vote of thanks to Dr. Biernacki.

Laryngological Society of London.—A meeting of this society was held on June 7th, Dr. Cresswell Baber, the President, being in the chair.—Dr. de Havilland Hall showed a case of Laryngeal Ulceration which was thought to be due to tubercle engrafted on old syphilis.—Dr. StClair Thomson showed a case of a Malignant Growth of the Larynx.—Dr. StClair Thomson showed one case and Dr. H. Tilley three cases of Frontal Sinus Suppuration cured by external operation.—Dr. Herbert Tilley showed two cases in which Thyrotomy had been performed some years previously for malignant disease; no recurrence had taken place in either case.—Dr. Furniss Potter showed a case of Infiltration of the Left Vocal Cord, probably tuberculous in nature.—Dr. McKenzie Johnston showed a specimen of Sarcoma of the Tonsil which had been removed by an extensive external operation with complete success. He also showed a specimen of Adenoid Growth in which there was a Large Cyst containing Cheesy Material.—Dr. J. Donelan showed a drawing of an Aortic Aneurysm, the only symptom of which had been paralysis of the left vocal cord.—Dr. FitzGerald Powell showed a case of Separation of the Upper Lateral Cartilages of the Nose secondary to Injury and Abscess.—Mr. Walter Spencer showed a case of Ulceration of the Septum.—Mr. A. Hudson exhibited an Apparatus for Vibratory Massage.—Sir Felix Semon showed three cases of Bilateral Abductor Paralysis in Tabes Dorsalis. In one case the inspiratory inward movements of the cords had ceased after tracheotomy, which seemed to add weight to the view that such movements were mechanical in origin.

Neurological Society.—This society met on June 22nd at Manchester on the invitation of the Manchester members. Professor J. Dreschfeld acted as

President —Specimens were shown by Dr Bruce, Dr Judson Bury, Professor Delépine, Professor Dreschfeld, Dr Moore, Dr Mott, Dr Orr, Dr E S Reynolds, Professor Sherrington, Professor Stirling, Dr Trevelyan, Professor A H Young, Dr. Warrington, and Dr Williamson, and Clinical Cases were shown by Dr Ashby, Dr. Bury, Professor Dreschfeld, Dr N. C Haring, Dr Harris, Dr Dixon Mann, Dr Reynolds, and Dr Williamson —In the afternoon the society was entertained at the Royal Asylum, Cheadle, at the invitation of Dr. and Mrs Mould and the committee of management In the evening the members of the society dined at the Queen's Hotel

Reviews and Notices of Books.

Chloroform · a Manual for Students and Practitioners By EDWARD LAWRIE, M B Edin , M R C S Eng , Lieutenant-Colonel I M S , Residency Surgeon, Hyderabad London-J & A Churchill 1901. Pp 120 Diagrams 5s net

THE plan upon which this book is constructed is an excellent one An exposition of the physiological action of chloroform is first given, and upon the facts therein stated principles are enunciated which should, in the writer's view, control the administration of chloroform

In the introduction Lieutenant Colonel Lawrie gives a brief *résumé* of the history of the Hyderabad Commission, but omits adequate reference to the large amount of physiological work done by various workers in elucidation of the action of chloroform Practically his teaching is summed up in these quotations "The action of chloroform is to lower the blood pressure with first unconsciousness, then anæsthesia, then stoppage of the respiration, and then stoppage of the heart" (p 23) "Other things being equal, the more concentrated the chloroform the more rapid the fall, and conversely" "When chloroform is sent to the heart alone it produces no effect: it has no direct action on the heart" (p 24) "When it is sent to the brain alone its usual action is exhibited—viz , lowering of blood pressure, with first insensibility, then anæsthesia, then stoppage of the respiration, and then stoppage of the heart" The vaso motor portion of the fall of the blood pressure under chloroform he considers to be entirely free from danger The fall of blood pressure he regards as being first due to vaso motor causes and then to "weakening of the heart" through narcosis of the respiratory centre This second factor, he admits, "is dangerous, and if chloroform is pushed as far as this stage there comes a time—not easy to define because of the impossibility in practice of drawing a distinct line between the termination of the vaso motor and the commencement of the cardiac falls—when the blood pressure and respiration will no longer be restored spontaneously, although the heart may continue to beat after the breathing has stopped" (p 28) It must, however, be remembered that any distinction drawn between the fall of blood pressure due to vaso motor action and to cardiac weakness and failure is an arbitrary one and is not recognised by physiologists Even the diagrams of tracings given in the book appear to us to support the contention that a continuous fall occurs due to the gradual narcotisation of the medullary centres and shown by the vaso-motor fall That any lowering of the blood pressure is harmless is, we think, open to question The danger is seen more and more as the blood pressure lessens and this Lieutenant Colonel Lawrie admits, only he declines to regard its origin as vaso-motorial Luckily, the discrepancies, grave as they are, between the author's physiological excursions and those of the physiologists do not affect the practical side of his book He is a severe critic on others and will probably be prepared to meet with equally strenuous criticism from those physiologists whose work he impugns and upon whose treatment of himself he animadverts

Leaving the purely controversial passages of the book we pass to what constitutes the best part of a most valuable exposition of the practical side of the subject In Part I a really admirable account is given of the physiological action of chloroform In it we find plainly stated the dual danger arising from the use of that anæsthetic—viz , that due to the fall of blood pressure and that incident to interference with respiration On p 32 the weakening effect upon the heart brought about by struggling and breath holding is insisted upon and on p 63 the same subject is looked at from the practical side, and respiratory embarrassment is shown to be the case of heart failure in such conditions as diphtheria, empyema, chronic alcoholism, and renal disease Throughout Lieutenant-Colonel Lawrie's practical rules one is struck again and again by the fact that his clinical acumen often leads him to warn against some of the perils which are minimised when he treats his subject as a controversialist

The directions in Part II , which applies physiology to practice, are very good and deserve the closest study The dangers of over dosage leading to excessive fall of blood-pressure are well put To many it will appear unnecessary at the present day to insist upon the pulse being neglected as a guide during chloroform giving, while the adoption of the routine use of morphine injection during chloroform narcosis is one to which many practical surgeons will take exception Although we are told that the rules given practically constitute Syme's method we confess that it is difficult to recognise in Lieutenant-Colonel Lawrie's precise rules, his measured quantities, and repeated reference to the dangers of falling blood pressure, the rough and ready method which was in vogue in the time of Syme The plan Lieutenant-Colonel Lawrie recommends in the instance of children contravenes his principles in many important ways and is, we submit, dangerous What is, however, beyond all praise is the insistence in his pages upon the absolute necessity for the chloroformist to give his undivided attention to his task To this and to the rule that irregular breathing, struggling, and holding of the breath are danger signals and that no chloroform must be given until they have ceased and the *colour of the face* is normal, we venture to think Lieutenant Colonel Lawrie owes much of his success as a chloroformist His rules with regard to chloroform in midwifery are those usually adopted It has been the custom, however, departing from the teaching of Snow, to regard *partial* narcosis as unsafe for even short operations and especially so in the case of dentistry Lieutenant-Colonel Lawrie does not follow this custom He believes in partial anæsthesia, he does not admit any danger of shock to the partially chloroformed patient, and he regards chloroform as a better anæsthetic for dental operations than nitrous oxide gas With the reservations indicated we have no hesitation in commending Lieutenant Colonel Lawrie's book on chloroform as one of the best we have seen and as a most admirable guide to the use of that anæsthetic If we cannot admit all the author's theory we can in most cases heartily accept his practice

Clinical Examination of the Urine and Urinary Diagnosis By J BERGEN OGDEN M D , Instructor in Chemistry, Harvard University Medical School London and Philadelphia W B Saunders and Co 1900 Illustrated Pp 416 Price 12s 6d

THIS volume is intended as a clinical guide for the use of practitioners and students of medicine and surgery, and the aim of the author has been to present in as concise a manner as possible the chemistry of the urine and its relation to physiological processes, the most approved methods of analysis, both qualitative and quantitative, and the diagnosis of diseases and disturbances of the kidneys and urinary passages We may congratulate the author on the success of his endeavours and an excellent manual on the examination of the urine for clinical purposes is the result.

The work is divided into two parts. In the first the chemical and microscopic methods of examination are described, and numerous illustrations, many of which are original, have been introduced, thus greatly adding to the value of the letterpress. The clinical conclusions that may be arrived at are clearly and concisely stated and all the matters dealt with are fully up-to-date.

In the second part of the book especial attention has been directed to diagnosis, the various pathological conditions of the kidney are brought under review, and the differential diagnosis of disturbances and diseases of the kidneys and urinary passages is discussed, whether those diseases are local or general, medical or surgical. A brief enumeration of the prominent clinical symptoms of each disease is given, and, finally, there is a useful chapter on the Urine in Diseases outside the Urinary Tract. An account is given of the characters of the urine in such diseases as enteric fever, pneumonia, and acute yellow atrophy of the liver. These phenomena are found described in most text-books on medicine under the various diseases in which they occur, but it is a matter of considerable convenience for reference to have them collected together as is done in Dr. Ogden's book.

We consider this manual to have been well compiled and the author's own experience, so clearly stated, renders the volume a useful one both for study and reference.

Atlas und Grundriss der Ohrenheilkunde. Untermitwirkung von Professor A. POLITZER in Wien. Herausgegeben von Dr. GUSTAV BRUHL, Ohrenartz in Berlin. Mit 244 farbingen Abbildungen auf 39 Tafeln nach Original Quarellen von Maler G. HAMMERSCHMIDT und 99 Text-Abbildungen. (*Atlas and Essentials of Diseases of the Ear.* Under the supervision of Professor A. POLITZER of Vienna. Edited by Dr. GUSTAV BRUHL, Aurist in Berlin. With 244 Coloured Drawings in 39 Plates from original dissections, by G. HAMMERSCHMIDT, Artist, and 99 Engravings in the text.) München: J. F. Lehmanns. 1901. Pp. 284. Price 12 marks.

DR. BRÜHL has given us an extremely beautiful atlas which embraces both the normal and pathological states of the ear and temporal bone. In his work he had the advantage of Professor Politzer's advice and assistance, and that alone is a sure guarantee of the quality of the book; it amply supplied that want of personal experience that Dr. Brühl's age would otherwise have entailed.

The illustrations of the normal bone are excellent and in Table 8 are drawings of two temporals, bones showing the position of the labyrinth; these bones had been decalcified and the labyrinth filled with metallic mercury, a method which has been applied also by Dr. Brühl to the accessory sinuses of the nose and depicted in Table 12, which will be a most useful plate for careful study.

The parts exposed in operations for intracranial lesions secondary to suppurative disease of the middle-ear are shown in Table 12 both before and after removal of the dura mater and will be a boon to those who for the first time find themselves called upon to deal with a case necessitating opening the skull in the neighbourhood of the ear.

Tables 36 and 39 consist of 48 drawings of morbid conditions of the tympanic membrane which have been selected with great skill and judgment; from them the practitioner will derive a knowledge hard to obtain by other means and will also have a handy and reliable guide to assist him in recognising and classifying what he sees by means of the speculum.

The plates showing microscopical preparations of the normal histology and pathology are very good, but if anything show conditions too rare to be of much service to any save the aural pathologist, but to those unable themselves to possess the actual preparations they will render clear the minute structure of the parts.

The drawings are taken from specimens in possession of Professor Politzer and of Dr. Brühl and the source indicated respectively by (P.) and (B.). The whole of Plates 38 and 39 are by Dr. Brühl, but the remainder are drawn by an artist, Herr G. Hammerschmidt.

Dr. Brühl devotes 62 pages to the Anatomy and Physiology of the Ear and illustrates it with some particularly lucid diagrams, all of which will render the subject clearer to the student. In this section a diagram of the cochlea deserves attention; it shows the parts of the organ of Corti with the musical notes with which they are connected according to Helmholtz, and from which the observer is able to deduct the particular part in which the lesion lies, though it is not, unfortunately, any aid in treating deafness.

In the chapter on Examination of Cases the most minute instructions are given—in fact, the great attention paid to this subject in German text-books is worthy of imitation. The general present state is to be noted, hints are afforded as to what is noteworthy and to what each sign may point, thus, icterus suggests pyæmia, and facial palsy caries. In the text Dr. Brühl indulges freely in abbreviations which naturally do not assist the English reader unless his knowledge of German is fairly good. In the use of the Siegle's speculum Dr. Brühl indicates the information to be derived and how to obtain it. Dr. Brühl naturally follows in Professor Politzer's footsteps as to the various indications for the use of Politzer's method and of the catheter to the middle-ear, as he, indeed, follows his teacher throughout, and nowhere is it more marked than in his descriptions of intra-tympanic operations.

As an illustrated text-book of the essentials of aural therapeutics Dr. Brühl's work is most useful and practical; it is a pleasant book to refer to and will be of considerable value to teachers no less than to students; it surpasses any previous work of the kind in its illustrations, is compact and well got up, and reflects great credit of all concerned in its production.

LIBRARY TABLE.

The Child: His Nature and Nurture. By W. B. DRUMMOND, B.M., C.M., M.R.C.P. Edin. Temple Primer Series. London: J. M. Dent. 1900. Pp. 146. Price 1s.—This recent addition to the Temple primers is intended as an introduction to the study of the physical and mental development of the child. Though quite elementary in scope it is thoroughly practical in its aims and should be of the greatest assistance to teachers and others who have the charge of young children. Dr. Drummond writes in an elegant style, and considering the small space at his disposal he has managed to condense an enormous amount of information within the narrow limits of 146 pages without at any time attempting a mere abstract or epitome of the subject. For many years there has been developing in our midst a new conception of education which looks to the individual to be educated and not to the knowledge to be crammed into the learner. To Pestalozzi and to Froebel is chiefly due the crystallising of the method in what is now known as the kindergarten system, and this method in all its latest developments forms the text of Dr. Drummond's observations. He explains very fully how the senses, the emotions, the intellect, and the will may be directed into the best paths and how bad habits may be prevented and the physical and moral welfare of the growing child best encouraged. Child study is a comparatively new branch of education and in this country has hardly yet reached the stage of development to which it has attained in Germany and America as regards the intellectual side and in Sweden as regards the physical side. This little work, which is within the reach of all who care to study the subject, should act as a real and beneficial stimulus to this most important branch of education.

The Extermination of Love. By E. GERARD. Edinburgh and London: William Blackwood and Sons. 1901. Pp. 322. Price 6*s.*—This book is described as a fragmentary study in erotics and the description fits it very well. The hero is a visionary scientific enthusiast who marries a girl of about 17 years, and who would have entirely ignored his marital duties on the bridal night had he not been primed with champagne, a beverage which he is made to partake of under the impression that it was water. Owing either to the champagne or to the young mother having been nourished after Professor "Henker's" theories, the offspring turned out a girl instead of a boy, and recalled in her appearance the various fruits and vegetables upon which her mother had been fed. The end of the book is that the hero, Dr. Peterstorff, gives a lecture at a medical congress upon a serum by which he hopes to exterminate love. At the ball which follows the lecture he becomes involved in a duel and is wounded. He is trephined and a cerebral tumour is discovered which is removed. He recovers both his health and his senses at the end of March, with the result that in the spring of the following year his wife has twins, "rosy, dark-eyed cherubs, true children of love." This is the story, and a very silly one it is.

B. Bradshaw's Dictionary of Bathing-places, &c. London: Kegan Paul, Trench, Trübner, and Co, Limited. 1900 Pp. 414. Price 3*s.* 6*d.*—This useful little publication comprises a vast amount of information upon baths, mineral waters, "air cures," and the like. So far as we can test it the information seems trustworthy. The "suggestions" for travellers are very good, and we are pleased to see recognition of the fact that a natural mineral water is superior from a therapeutic point of view to an artificially prepared one, even though the latter may be chemically indistinguishable from the former. We may again call the editor's attention to the fact that jaundice is not a disease.

Burdett's Official Nursing Directory, 1901. By Sir HENRY BURDETT, K.C.B. London: The Scientific Press, Limited. Pp 420. Price 3*s.*—This Directory is, as is explained in the preface, "official" only in the sense "that the information given in it relating to nurses is either derived from official sources or has been verified by competent authorities." It is, however, a useful book, and besides the directory of nurses it contains a valuable abstract of laws affecting the nursing profession and a list of training schools, together with a table of provident funds, examining bodies, and associations for the benefit of nurses.

Beauty Adorned. By Mrs. HUMPHRY. London: T Fisher Unwin. 1901. Pp. 316. Price 1*s.*—Mrs. Humphry, who is the "Madge" so well known to readers of *Truth*, gives some very excellent advice in this little book about beauty and the matters which go to enhance and to preserve it. Her advice as to personal cleanliness, washing, and taking care of the hair: upon dress, food, and drink is very good, and we are glad to see that she gives a very decided warning as to the use of celluloid combs (p. 25) To one passage in her book we must take exception. It appears on p. 59 and has reference to the choice of spectacles. "The choice of spectacles should always be made under the advice of an experienced optician. . .... He will also be able to advise his customers when a visit to an oculist is imperatively necessary." He might be able to do so, but we very much doubt whether he would. But it goes without saying that the choice of at any rate the first pair of spectacles should always be made upon the advice of a duly qualified medical man who has studied diseases of the eye and the various errors of refraction. Mrs. Humphry also recommends (p. 61) that when anything gets into the eye "it is advisable to go at once to a chemist or a doctor." With this advice, so far as concerns a chemist, we cannot agree. The eye is far too delicate and valuable an organ to be meddled with by amateur practitioners, whether opticians or chemists. Apart from these passages, however, Mrs. Humphry's advice is sound.

Cerebral Science: Studies in Anatomical Psychology. A Book for Artists, Physicians, and Teachers. By WALLACE WOOD, M.D., Professor of History of Art in the New York University. London: Baillière, Tindall, and Cox. 1901. Pp. 128. Price 3*s.* 6*d.* net.—Dr. Wallace Wood's effusions, if somewhat incomprehensible, are amusing. The last work of his which we saw was a little pamphlet on Love which is situated in the anterior metopic lobule.[1] We do not quite understand what the work now before us is about, but according to Dr. Wood's preface, "out of the theoretical science of comparative psychology, founded upon comparison of the brain gyres, will grow the practical science ethology." The psychology of the lamb is thus described: "The sheep is a blockhead, doubtless, and the tiger has a fine intellect—that is to say, a fine intellect posterior—that is, a sanguinary intellect; but in the blockhead of the lamb is a divine spark, a magic light by which he leads the procession forwards." Turn we now to the cat. "What qualities have made the Miow?" We should explain that Miow is Egyptian for cat. Dr. Wood goes on: "Sensitivity, sharp ears, sharp eyes, sharp nose, sharp tongue, sharp feelers, sharp tentacles, *akinoia* at its height. . .... Vigilance is a fine quality. The panther wakes while others sleep. The early bird catches the worm—foolish worm! foolish bird! ...... Heat is a fine property. The Miow has heat. ...... The griffers are nocturnes." We are obliged to Dr. Wood, but what *does* he mean?

JOURNALS AND MAGAZINES.

THE *Practitioner* this month somewhat belies its title. The number is almost entirely engrossed with the subject of hospital management, a topic with regard to which the average practitioner, once his student days are over, can spare but little time. To such, however, as can busy themselves with the internal affairs of hospitals the *Practitioner* provides a series of articles dealing with the matter from all the chief points of view. The views of a hospital physician are given by *Dr. Issambard Owen and Dr. A. E. Sansom* and others Mr. Charles Burt and Mr. John Murray represent lay committee-men, and the Rev. Henry Wace also writes on the subject. A few pages on Diseases of the Digestive Organs by Dr. H. D. Rolleston represent the technical matter of this number. Air-swallowing or aërophagy and black vomiting in appendicitis are among the subjects that Dr. Rolleston deals with

Medical Magazine.—The early recognition of pulmonary tuberculosis is an important subject well considered by Dr. J. E. Squire in the June number. Dr. Squire points out how easy it may be to miss vague indications given by the earliest stages of pulmonary tuberculosis. With no physical signs to direct his suspicions the practitioner is apt to miss the meaning of anæmia, gastric disturbances or irregular temperatures really indicating the onset of phthisis. The extent to which confirmatory evidence may be obtained from tuberculin, skiagraphy, or bacteriological examinations of sputum is also discussed. Dr. F. Parkes Weber provides an interesting article on Fatness, Overweight, and Life Assurance, and Mr. J. Foster Palmer's valedictory address to the Chelsea Clinical Society is a contribution that gives some pleasant enough learned levity. The late Sir B. W. Richardson and his work are the theme of an enthusiastic, if somewhat ill-proportioned, article. The toxic origin of neurasthenia and melancholia is the most important matter alluded to in the annotations.

---

[1] THE LANCET, August 25th, 1900, p 597.

Mercy and Truth.—In the June number there is an illustrated article of several pages in length entitled "Work among Women in Yezd," a Persian city, the writers being Mrs. Malcolm, M.B., Miss Mary Bird, and Miss Brighty.

New Inventions.

A MODIFIED PLASTER SPLINT.

The splint is made of two pieces of ordinary thin flannel and is stiffened by pieces of flannel soaked in plaster or, better still, by strips of plaster bandage, soaked and laid evenly between the layers of the flannel. The larger piece of flannel is wide enough to make the splint sufficiently long and long enough to encircle the limb and to allow each end to be turned back at least half way round the limb again. The second piece of flannel is of the same width as the first but only long enough to extend halfway round the limb. These two pieces are sewn together by the middle along the whole width (see Fig. 1 at o). Now the seam joining the two pieces is tucked in along the whole width and sewn along the line *b* (see Fig. 2). This fold is kept towards the limb and is placed where the hinge of the splint is wanted. The fold in practice is less than a quarter of an inch deep and is not felt by the patient, especially as no plaster is laid over it. If it is made deep the hinge of the splint will be too free. The fold should be exactly in the middle of the front or side of the limb, as the case may be, all the way down. The ends of the larger piece of flannel should then be carried over and tacked together exactly opposite the hinge, the flannel being pulled fairly tight over the limb and, if necessary, V-pieces cut out to make it fit neatly. There are then four flaps of flannel, two of which will be turned over the front of the limb and two over the back. All is then ready for the plaster. The strips should be well soaked and laid longitudinally on the flannel sheathing the limb, care being taken that the strips extend well into the grooves formed by the junction of the flaps with the sheath. When enough is laid on for the purpose the flaps should be turned back over the plaster and fixed with a bandage. In practice it is found that the splint is more comfortable if the plaster strips are an inch or so short at each end, so that the sheath and flaps are somewhat longer than the plaster stiffening. To remove the splint take off the bandages and cut the tacking cotton along the groove on either side. The splint will open altogether in front but at the back it will only open down to the hinge.

Fig. 1.

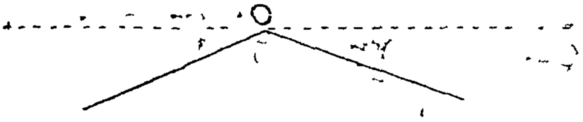

Fig. 2.

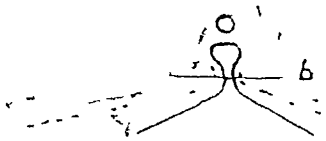

The dotted line shows the first piece of flannel; the unbroken line shows the second piece.

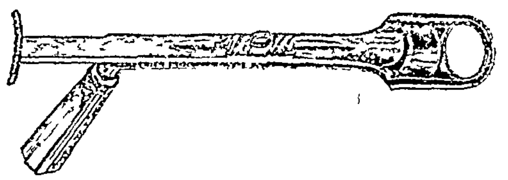
THE ANATOMICAL TONSILLOTOME.

One frequently sees even expert operators return to the charge and have to make a second cut with the tonsillotome before all the enlargement is satisfactorily removed. The explanation of this is, I think, to be found in the shape of the opening in the instrument not being of such a nature as to correspond anatomically with the form of the tonsil. The tonsil is elongated vertically, even when enlarged, and unless the guillotine opening is of such a shape as to include the whole of the enlargement there is always sure to be more or less left behind; especially is the lower point of the tonsil unremoved and this continues to cause irritation and cough. This is obviated by the use of the "anatomical" tonsillotome. Messrs. Beauchamp and Co., surgical instrument makers, West Smithfield, London, E.C., have made the instrument for me.



Welbeck-street, W. Wm. Stuart-Low, F.R.C.S. Eng.

JEQUIRITOL.

We have received a box containing samples of jequiritol (Merck) from Messrs. Merck, prepared according to the directions of Dr. Römer of Würzburg. It will be remembered that some years ago an infusion of the seeds of the *Abrus precatorius*, which are small, subspherical, and red, with a black spot at one end, was strongly recommended by M. Wecker of Paris as an efficient agent in the cure of purulent ophthalmia of adults and of the granulations that are so common in that affection. Its curative effects were stated to be due to the circumstance that the infusion excited violent inflammation of a different kind from that causing or accompanying purulent ophthalmia, which was accordingly arrested whilst the granulations underwent absorption. The experience of many surgeons, however, rendered it certain that the inflammation excited by jequiritol infusion was not itself unattended by danger and when cases of deep ulceration of the cornea or even of sloughing of that membrane were met with it was felt by most ophthalmic surgeons that it was too dangerous a remedy to be prescribed until some means were found to regulate its action. The experiments of Ehrlich in 1850 led him to the conclusion that animals could be rendered immune to the action of abrin and that they then generated in their systems a specific antitoxin. This agent, however, could not be preserved and quickly lost its activity. The pharmaceutical firm of Merck, however, continued Ehrlich's researches and have produced, and have been able to preserve, a special antitoxin which, introduced into the blood, enables a dog or rabbit to resist very powerful doses of jequiritol applied to the eye—doses that would certainly destroy the eye in animals not rendered immune. The jequiritol serum obtained by Messrs. Merck has been experimented with by Dr. Romer who has found that in the first place it possesses, when locally applied, a distinctly marked curative action on inflamed conjunctiva whilst it is itself innocuous. Experiments made by Dr. Romer, in conjunction with Dr. Hess, have satisfied both observers that it is the best means for the removal of nebulæ of the cornea. It accomplishes this by first causing serous transudation into the substance of the cornea, and then as the fluid is absorbed the nebula disappears. By increasing the strength of the doses of jequiritol, which can be accomplished with great exactness, the precise degree of inflammation can be determined. The tubes are numbered from one to four, and in cases requiring this form of treatment one or several drops of the tube marked 1 are introduced into the conjunctival sac; if in the course of 24 hours no inflammation follows a drop or two of the tube marked 2 are instilled, and so on until the desired degree of inflammation with delicate croupous membrane and œdema of the lids is excited. In the same box are contained some small capillary tubes containing jequiritol serum and in the event of the inflammation of the conjunctiva induced by the jequiritol being too strong a little of the jequiritol serum is dropped into the eye and the inflammation at once subsides. Dr. Römer finds that this treatment is most useful in children with tuberculous and eczematous pannus, vision being rapidly and greatly improved

LONDON: SATURDAY, JUNE 29, 1901.

The National Hospital for the Paralysed and Epileptic: Report of the Committee of Inquiry.

WE publish to-day the gist of the report of the committee of inquiry chosen by a committee of governors of the National Hospital for the Paralysed and Epileptic, Queen-square, who were appointed for that purpose at a meeting of governors held in March. A full report of the proceedings at this meeting appeared at the time in our columns.[1] Our readers will remember that this was the outcome of a long and, on the part of the Board at least, at times acrimonious discussion, arising primarily out of a demand on the part of the medical staff for direct representation on the Board of Management. The demand had been made several times in the last 10 years but without effect. Various alternative schemes had been tried, but these had either been found unsatisfactory or had been summarily discontinued by the Board without explanation. The staff felt in the end compelled to address themselves directly to the governors and to call their attention to the faulty administration of the hospital under the present system, to the inadequacy of the nursing staff for the duties required of them, to the insufficient supply of linen, to the unsatisfactory character of the food supplied both to patients and to nurses, and to the inadequate nature of the accommodation provided for the latter. They also drew the attention of the governors to the office of secretary and general director as one which was anomalous and which had proved prejudicial to the interests of the hospital.

Such were the allegations which the committee of inquiry had to consider and to examine. That their task was no light one, and that they have spared neither time nor trouble in carrying it out, will be evident to anyone who carefully examines the record of their findings. In the first place they find that the medical committee were justified in addressing their statement directly to the governors without previously communicating with the Board of Management. The significance of such a finding will not be lost upon anyone who has interested himself in this controversy. With regard to the allegations in this statement, they find that at the beginning of last year the supplies to particular wards fell short more often than ought to have been the case, and at that time also the quality of certain articles of diet afforded good ground for complaint. They also find that the milk was formerly watered. It is also found that even now, although there has been an increase since the beginning of 1900, the nursing staff, notwithstanding that its members are zealous and, as a rule, efficient, is not adequate to the duties required of it and that the accommodation provided for some of the nurses is unsatisfactory. The supply of linen to the wards they also consider to be deficient, and that this is especially the case with regard to the draw-sheets. The latter also are badly and insufficiently washed, a circumstance which the members of the committee verified by actual inspection.

On the matter of the representation of the staff the report pronounces no uncertain verdict. It is recommended that the Board of Management should be increased by the addition of two members chosen by the medical committee from the medical staff—the exact mode and degree of representation asked for by the medical committee—and the opinion is expressed that this mode of representation is a very proper one and the smallest concession which is reasonable. The committee also express their belief that if direct representation of the medical staff had been part of the original constitution of the hospital the present schism in the body would never have arisen or would speedily have been healed.

With regard to the office of secretary and general director the abolition of the office is recommended and alternative schemes for securing efficient medical and administrative control are suggested. The committee express grave doubts whether such an office could ever be satisfactory in such an institution. But if it was to be satisfactory it could only be so under conditions of greater watchfulness and interest on the part of the Board than obtained at the National Hospital for the Paralysed and Epileptic and in the hands of a man who was possessed of tact and judgment as well as of ability, and who carefully kept himself from exceeding the powers with which he was invested. "Unfortunately," they significantly add, "in the present case none of these conditions have existed." Of the energy and ability which the present incumbent of the office, Mr. BURFORD RAWLINGS, has brought to the service of the hospital the committee show adequate appreciation, and they direct attention to the claims which he has on the gratitude of the institution should any changes be instituted as a result of their report. They further point out in this connexion that in most, perhaps in all, of his dealings with the medical staff the secretary and general director received the approval and support of the Board of Management, and that on them rather than on him rests the responsibility for the part which he played. As indicating the peculiar duties which Mr. RAWLINGS arrogated to himself, we need only mention his declining to deliver to the chairman of the Board a sealed letter from a member of the staff and his refusal to admit a patient recommended as suitable by both a physician and a surgeon to the hospital on the ground that the applicant was in his opinion an idiot. The case was really one of traumatic epilepsy and was subsequently operated on successfully at another institution.

It is not quite easy to understand or to appreciate the position and acts of the Board of Management of this hospital. This body consists of 12 members. The average attendance at its monthly meetings was five. It also constituted a house committee, which should have met once a fortnight—26 times a year. In two years this committee met 29 times (instead of 52), and at 18 of these "meetings" only one member was present! There was also a finance committee, of the proceedings of which no record was kept. This committee apparently looked at and initialed the tradesmen's bills, one member formed a quorum, and apparently a quorum was sometimes obtained. Of the duties usually performed by a finance committee of a hospital this committee had apparently no knowledge. If the secretary and general director had on many occasions shown a tendency to amplify his jurisdiction beyond its legitimate bounds the Board of Management cannot be accused of having done more than its duty.

---

[1] THE LANCET, March 30th, 1901, p. 931.

With the matters of detail concerned with structural alterations this is not the time to deal. And we need only refer to the guarded pronouncement of the committee in reference to out-patients' payments and their recommendation as to some of the financial arrangements with regard to the funds of the charity. All that we have to do at present is to point out that a grave indictment has been brought against the Board of Management of this hospital; that this has been proved in all its essential points, and that the process has revealed a state of matters urgently calling for reform. The report indicates the lines on which reform should proceed. We do not doubt that the governors, with whom the ultimate responsibility rests, will respond to the call made upon them to reform the institution. Many of the rules and practices of the hospital, as the report points out, are such as to seem almost like an attempt to drown the voices of the governors. Had this not been so reform would have come long ago. Indeed, the necessity for it might never have arisen. But it is not too late, and we are sure that the whole medical profession will unite with us in congratulating the medical staff upon their long and strenuous fight to establish on broad foundations an institution for which they have already done so much, and in expressing the hope that the governors, by adopting the report which we have been considering, may ensure the continuance of the relief afforded at this hospital to a peculiarly distressing class of maladies and at the same time of the opportunities for obtaining a still more intimate and profound knowledge of their nature and treatment.

Local Authorities and Tuberculosis.

THE Camberwell Borough Council has resolved to take an important step, and one which will place it in the position of a pioneer of sanitary reform among the councils of the new metropolitan boroughs, a position which, it claims, was occupied with relation to vestries by the late Vestry of Camberwell. It proposes to prosecute, or rather to prepare to prosecute, vendors of tuberculous milk under the sixth section of the Food and Drugs Act for selling milk not of the "nature, quality, and substance" of that demanded by the purchaser. In order to prevent the infliction of hardship upon the milk-vendors by springing upon them a series of such prosecutions without warning it will not initiate these proceedings at present, but will in the meanwhile cause samples of milk to be taken and examined, so that the sellers may be made aware of the results of such examination and may be enabled to make arrangements for the obtaining of a healthy milk-supply should it be found necessary for them to do so. The resolution passed by the Camberwell Borough Council embodied the recommendation of its Public Health Committee, which in its turn acted upon a report presented to it by Mr. E. C. BOUSFIELD, its bacteriologist, who set out the facts and made his proposal with commendable clearness and succinctness.

We have every sympathy with the movement that seems thus seriously about to be initiated. The sale of tuberculous milk constitutes a real danger, particularly to the young and in districts in which milk businesses are conducted upon a small scale by tradesmen who in no way control, and who do not at present seek to control, their sources of supply. Large dairy companies who purchase their milk by contract with farmers selected by them can and do bind the farmers to permit their farms to be periodically inspected in order that any contamination of the milk in the process of feeding or milking the cows or of sending the milk to the distributing agents may be, if possible, avoided. In such cases as these any milk found to contain germs of tuberculous disease could easily, or comparatively easily, be traced to the particular cow or cows infected. In the case of the small trader the matter will perhaps be more difficult, while the prevention of a repetition of the danger may also not be so easy. We need not go into details, but obviously if the milk does not reach the retailer in the churn in which it originally leaves the farm will be difficult to follow it back to the cow or cows which produced it, and it is also obviously possible for dealers deliberately to conceal and to disguise its origin where it is worth their while to do so. However, there can be no doubt that the first step in the path of progress will be made when it has been established that the vendor of tuberculous milk has been, and, if detected, will be, convicted and punished for selling that which is not of the nature, substance, and quality of the article demanded by the purchaser of "milk." As to whether this end will be attained without further difficulty by the Camberwell Borough Council we are not in a position to say. That body will no doubt consult its legal advisers before it takes the contemplated step, and its legal advisers will have before them the case of GOULDER *v.* ROOK and three other similar cases argued before the Divisional Court on May 13th last, and referred to by Mr. BOUSFIELD. These cases have not yet been reported, except in the newspapers, and the *Times*' account of them does not contain observations mentioned by Mr. BOUSFIELD as having been made by Lord ALVERSTONE in the course of the hearing, to the effect, apparently, that vendors of tuberculous milk might be convicted under the sixth section of the Food and Drugs Act, just as certain vendors of arsenical beer had been in the cases then before the court. Lord ALVERSTONE, according to the *Times*, said that the question was one of fact, that the magistrates had found as a fact that the beer was not of the nature, substance, and quality of the article demanded, and that he could not say that there was no evidence in support of that finding. He did not, however, suggest that any accidental presence of deleterious matter in an article of food would necessarily make it not of the nature, substance, and quality demanded, and he added that each case must stand by itself; while finally, of the four appeals before the court, two were allowed, one was dismissed, and one was sent back to the magistrates for conviction.

We must not be taken as disparaging or in any way seeking to discourage the action of the Camberwell Borough Council in writing thus of its determination to check as far as it can the spread of tuberculosis We would rather express our regret that the law should not be clearer on such subjects and that it should have to be elucidated by *expensive trials* and appeals. But whether an *obiter dictum* of Lord ALVERSTONE justifies proceedings against vendors of tuberculous milk under the sixth section of the Food and Drugs Act or not, we would point out that the Camberwell Borough Council will have put itself in a far stronger position than that occupied by those who prosecuted the retailers of arsenical beer if it adheres to the course which Mr. BOUSFIELD proposed to it. The beer-sellers could urge *in defence or in mitigation of penalties that they knew* nothing of the arsenic in the beer that they dealt in. The Camberwell Borough Council proposes to warn sellers of tuberculous milk of what they are selling before taking legal proceedings; and whether the Food and Drugs Act applies or not we should be sorry to suggest that the law of England cannot prevent and punish the deliberate and conscious sale of milk laden with the germs of a deadly disease.

◆

The Inclusion of Anæsthetics in the Medical Curriculum.

THE historian who deals with the changes of medical thought during the latter half of the Victorian era will find much to say concerning the increased recognition of the importance of the administration of anæsthetics For some time after SIMPSON'S great discovery and the revival of the use of ether as an anæsthetic it became at first doubtful whether anæsthesia had "come to stay," and when that question had been definitely settled in the affirmative little or no progress was made in systematising the methods employed or determining who should be their exponents In the United Kingdom specialisation has answered the problem as far as the hospitals are concerned. In the country towns and outlying villages no equipment of this nature can ever exist The practitioner must be prepared to undertake the giving of anæsthetics among the multifarious duties of his daily round. We have pointed out on more than one occasion, and notably in a leading article published in THE LANCET of Oct 27th, 1900, p. 1215, that but few men have ever had preliminary training in anæsthetics, and the majority must therefore be placed at a great disadvantage when called upon to give chloroform or ether. Too many students fail to realise that their hospital career is all too brief and the chances given to them during it pass never to return. In a paper read recently before the Society of Anæsthetists the Vice President, Dr. DUDLEY BUXTON, urged that every student should be compelled to satisfy the Board of Examiners as to competence in giving anæsthetics before being allowed to practise his profession. This paper and the discussion which followed revealed the fact, which we believe has not been sufficiently appreciated, that really only a very small percentage of our medical students are sufficiently taught the use of anæsthetics. The machinery for teaching exists, and in most, if not all, of the London hospitals the accredited anæsthetists actually lecture and give demonstrations to such students as care to attend. A certain number of students ambitious to hold hospital appointments are obliged to produce certificates of their competence before they can take up their hospital duties, but for the majority no such compulsion has been practised

We understand, however, that this serious defect in our medical curriculum is shortly to be amended The various hospital authorities have been approached by the English Royal Colleges and requested to furnish information as to what instruction is at present given in the administration of anæsthetics, and we believe that it is an open secret that ere long it is proposed to include this subject in the compulsory curriculum and to insist upon every student furnishing evidence of his competence to conduct an ordinary case of anæsthesia before his admission to a qualifying examination. The re-organised University of London is also admitting teachers of this subject to the Faculty so that much has already been accomplished in the direction of placing this vitally important subject on all fours with the other courses of study at present embraced i the medical curriculum.

This is certainly matter for congratulation, for, as it has been insisted upon on many occasions in our columns, both the instruction in anæsthetics and the status of the teachers of that subject have been unfortunately too long neglected. The requirements of modern surgery necessitate not only the precision and accuracy of the operator but the efficient conduct of the anæsthesia The duration of an operation at the present day is unavoidably longer than it was in the days of LISTON, and not only is absolute anæsthesia requisite for the delicate manipulation of many surgical procedures—such, let us say, as of a gastro enterostomy—but in such cases the safety of the patient may depend on the knowledge, nerve, and expertness of the chloroformist. The day has passed when the senior student or any chance onlooker was entrusted with the task of producing and maintaining anæsthesia It is not too much to say that not only may the operation be marred and rendered impossible, but even the life of the patient may be sacrificed by the carelessness or inexpertness of the inexperienced anæsthetist It is recognised that to obtain even ordinary skill in managing a case of ether or chloroform narcosis a student must receive the most careful training and must, further, be taught the practice as well as the theory of his subject. At present most medical men only learn this after they commence practice, and so they seldom attain the nerve and experience which alone can make a reliable anæsthetist In the near future we may hope that every medical man will have acquired some acquaintance with the practice of producing anæsthesia while yet in the receptive stage of his student life. We do not wish to imply that there will no longer be need of the services of experts—men of wide and everyday experience in what is one of the most difficult and arduous duties of the medical profession—yet all students can be made competent They can learn to avoid the recklessness of ignorance and the equally dangerous timidity of inexperience, and this is a great gain alike to themselves and to the public at large.

The Guild of St. Luke and St. Luke's Day.

THE brethren and members of St. Luke's Guild comprise a large number of members of the profession, metropolitan and provincial. The annual service in St. Paul's Cathedral on or near St. Luke's Day (Oct. 18th) has become a hardy annual and a very successful one, the service being well rendered and the sermons, by special preachers wisely selected, excellent. But St. Paul's Cathedral is, after all, but a small part of the metropolis and London is a small part of the United Kingdom. Our London *confrères* number, according to the Medical Directory, 6211, those practising in the English provinces, Wales, Scotland, and Ireland, nearly treble this number, being in all 18,404. Many years ago, when Hospital Sunday was limited to Birmingham, it was suggested in THE LANCET that a Sunday set apart for the benefit of the medical charities throughout the length and breadth of the United Kingdom would have a very beneficial effect. The suggestion, however, has been found to be impracticable, local circumstances as to season and clerical and lay coöperation being so variable. These, however, do not apply to a more general recognition and observance of the feast of the patron saint of the medical profession, St. LUKE the Evangelist and Physician, described by St. PAUL as "the beloved physician." The date of the festival is opportune, being little more than a fortnight after the commencement of the medical year in England and the opening of the medical schools. Professors, lecturers, and students are gathered together, medical practitioners in general have returned home from the holidays, and St. LUKE'S Day comes to remind us of our duty as exemplified in the motto of King's College. The late Sir WILLIAM FERGUSSON seized upon this conjunction in his address when President of the British Medical Association at the annual meeting in London in 1873. "We have begun our work this morning holily under the Dome of St. Paul's," he happily observed, "let us conduct it wisely, and thus fulfil the well chosen motto for King's College, within whose walls we are now met, '*Sancte et sapienter*.'" The more general observance of St. Luke's Day would, without any encroachment upon the annual service at St. Paul's, be a most fitting sequel to the opening of the winter medical session at the different medical schools. It would be chimerical to suggest that every member of the medical profession should be a member of St. Luke's Guild—this is impossible. But a very large proportion of the medical practitioners in these kingdoms are members of the Church of England and many of them would gladly avail themselves of the opportunity of attending a special service on St. Luke's Day or, as might be preferable, the Sunday after. We learn that arrangements for this are being made in Liverpool, the second city in England. The Church of St. Luke was completed and consecrated in 1831. Whether its dedication to the patron saint of members of the healing art was accidental or designed cannot be stated, but it is significant that Rodney-street which closely adjoins it has for many years past comprised the residences of physicians, surgeons, and dentists. The church, moreover, is centrally situated and accessible from all parts of the city by electric tramcars. The Venerable Archdeacon MADDEN, the vicar of St. Luke's, is making the necessary arrangements for the holding of the service on the afternoon of Sunday, Oct. 20th. The sermon will be preached by the Right Rev. Dr. CHAVASSE, Lord Bishop of the diocese, and the occasion is being looked forward to in Liverpool with much interest.

Annotations.

"Ne quid nimis."

THE FACTORY BILL AND THE SANITATION OF POST-OFFICES.

AN amendment affecting the interests of a large body of medical men has been proposed to the Factory and Workshops Act Amendment Bill (1 Edward VII.), and we understand that Sir Walter Foster, M.P., has promised to give it his support. Its purport is to add to the text of Section 45 the following words:—

> "And also all Government offices and workshops or other premises used by the Crown or by any department of His Majesty's Government and whether such Government offices, workshops, or premises belong to the Crown or are only occupied by the department for the time being using the same."

This implies that all premises utilised by the postal authorities will be placed under a new and additional sanitary inspector of post-office buildings. Now there are about 600 postal medical officers in the United Kingdom. It is their business to act as sanitary inspectors of these buildings. Special instructions have been issued to each and all to watch over the sanitary conditions of the post-offices in their respective localities. If it could be shown that the postal medical officers had neglected to perform this duty then there might be some reason to appoint an official to overlook their work and to insist on a more strict observance of the rules. But such is in no wise the case. There is, on the contrary, every reason to believe that the postal medical officers are keenly alive to this most important duty. In another column we publish a letter which shows that in regard to accurate information it is not the local officials but rather the central authority which is at fault. It is a matter of difficulty to get correct information from the central authorities, for the statistics that have been given are unclassified. No one pretends that letter-carriers are especially susceptible to pulmonary tuberculosis. It is the letter-sorters, the clerks, and others who are confined indoors all day who become the victims of this disease to an extent which considerably exceeds the average of the general population; and it is the statistics relating to this particular class of workers which are needed and are not forthcoming. Nevertheless, the figures given, though they include all classes of workers engaged for the postal service, show that the deaths from pulmonary tuberculosis among them exceed considerably the general average. Therefore, we may conclude that there are sanitary defects in the buildings utilised by the postal administration. Now if it could be proved that the postal medical officers had taken no notice of these defects, or had never urged the necessity of improvements, then there would be good grounds for appointing controlling sanitary inspectors. But such is not the case. For instance, at the last annual meeting of the Association of British Postal Medical Officers, held in June, 1900, the following resolution was adopted and copies were sent to the Postmaster-General and to the Right Hon. R. W. Hanbury, M.P.:—

> "Having regard to the observations made by Mr. Hanbury in the House of Commons, in reply to Mr. Weir, on May 18th

Last, it is the opinion of this meeting of postal medical officers that the present position of medical officers is unsatisfactory when dealing with the sanitation of the post-office buildings for which they are held responsible, because sanitary defects, when reported upon by them, in many cases remain unremedied.

It is hereby suggested that it would be advantageous if Her Majesty's Office of Works, after conference with medical officers, were to carry out necessary sanitary recommendations made through the recognised departmental channels."

Here it may be explained that the Association of British Postal Medical Officers extends throughout the United Kingdom and that nearly every medical officer in the employ of the Post Office is a member of this association. Further, one of the objects of the members of this association is voluntarily to study and to consider all means by which they can discover, and all measures by which they can prevent, the spread of disease among the 160,000 employés of the British postal services. The association has, at its own expense, collected much information on this subject and has not lost any opportunity of bringing the facts thus collected to the notice of competent authorities. Under these conditions it is urged that the appointment of an outside sanitary inspector to visit and to examine the post-offices, &c., is an unnecessary expenditure of public funds and that this may occasion a considerable amount of friction. When the recommendations that have already repeatedly been made by the postal medical officers have been taken into account and carried out it will be time enough to move for further inspection should the measures proposed prove inefficacious. To appoint now another and a controlling class of inspectors seems to infer that the inspection as it now exists is inefficient, whereas the inefficiency rests in the fact that the recommendations made have not been carried out. Under such circumstances it is very natural that the postal medical officers should protest against the proposed amendment to the Bill now before Parliament, and we hope that their arguments will receive full consideration.

PSYCHOPATHIC HOSPITALS.

In the eighth annual report of the State Charities Aid Association of New York presented to the State Commission in Lunacy in November last, after referring to two distinct results which have after years of constant effort been attained —viz., economy of asylum administration and adequate provision against overcrowding of patients in institutions—the report deals with a scheme for founding psychopathic hospitals for the acutely insane in the State of New York. The curative treatment of insanity was as yet (said the report) in its infancy. The insane had been regarded for too long a period as persons for whom custodial care only was required. In many of the States of the Union numbers of them were still to be found in gaols and poorhouses. To promote the advancement of knowledge regarding treatment it was necessary to secure the best medical skill that the country afforded. If a hospital for the reception of a limited number of acute cases of insanity (say, 600) could be established at some place readily accessible from New York the association felt assured that it would receive freely the services of the most eminent alienists of New York who would gladly serve as attending and consulting physicians. Into such a hospital would be gathered all cases of supposed insanity and recent cases of certified insanity, and here they would be examined and classified by the attending physicians before being placed in suitable wards. Cases of general paralysis or other marked forms of incurable insanity would be sent to other institutions appropriate to such cases. Cases possibly curable would be kept for a limited period in the reception hospital until it was decided whether they could benefit by further stay and treatment or whether transfer to another institution was desirable. There would be an out-patient department connected with the hospital from which patients could be received into the wards and where students would have an opportunity to familiarise themselves with the diagnosis and treatment of the minor forms of mental alienation and disorder. The practitioner who was often called upon to treat such cases and whose knowledge regarding them was very slight could here acquire useful knowledge and experience. Under the roof of such a psychopathic hospital the already established pathological institute of the New York asylums would naturally find its home. The proposed reception hospitals, of which the first will be erected at Rochester, N.Y., are designed to form part of the existing State hospital system. Controlled by the same board of managers, they will be "in close touch with progressive scientific work wherever found, be that within or beyond the walls of the present buildings." It is finally pointed out that the scheme advocated is not entirely new. For many years such psychopathic hospital have been established in Vienna, Heidelberg, Strassburg, Leipsic, and other cities. That of Giessen, opened in 1896, is the most recent, and is considered to be the best by Dr. Frederick Peterson of New York who visited that and other institutions in 1899. Until overcrowding of patients is relieved there can be no proper classification and without proper classification but little progress can be made towards satisfactory treatment. The time has come when all efforts should be made to secure these ends—viz., the prevention of the preventable insanities and the proper classification and cure of the curable insanities. The provision of psychopathic hospitals was one of the means to such ends.

THE ORGANISATION OF A PURE MILK-SUPPLY.

It is undoubtedly a gain to public health that the supply of milk is being undertaken on a large scale, for the organisation of a large business is calculated to include arrangements for the scientific control of the purity of the milk, involving the employment of a scientific staff. Obviously these arrangements are beyond the capacity of the ordinary cowkeeper or milkman acting alone. The fact is, the production of milk has for too long been carried on in a rule-of-thumb way. Now, however, that it is known that milk is one of the most powerful factors amongst us as a carrier of disease it becomes incumbent upon all milk-producers upon their part to ensure, as far as possible, the supply of milk about which no suspicion can be reasonably entertained We are glad to think that our big dairy supply companies recognise this responsibility and accordingly spare no expense in taking precautions to secure the supply of milk derived from healthy cows. The Aylesbury Dairy Company inform us that they prepare a regular set of printed forms which have to be filled up by the various persons concerned in the production and consignment of milk. Thus on the application of a dairy farmer to be allowed to contract for the supply of milk he must fill up a form relating to the entire circumstances under which he can supply the milk. These circumstances are considered by the company and everything being satisfactory the farmer signs a contract subject to the farm being reported upon favourably by the medical officer of health of the district, and to the water-supply being passed by the company's resident analyst. Then, and not till then, is milk allowed to be sent to the company. These relations once established the farm is visited at least once monthly by the medical officer of health who has a form provided for him to fill up. Again, a form is provided for the veterinary surgeon in which he is to report the condition of every animal, and should the slightest suspicion of tuberculous disease be entertained the tuberculin test is applied and the result is reported. In the event of infectious sickness breaking out on the farm the milk is immediately stopped until a certificate is furnished from the medical officer of health to the effect that the company may continue to receive milk from the farm without danger to their customers. Lastly, in cases of infectious sickness occurring in the house of a customer delivery by the ordinary service is discontinued and all supplies are sent by special messenger. Precautions like these are admirable, and if strictly carried out would soon render the conveyance of disease by milk a thing of the past. We believe that the Aylesbury Dairy Company were amongst the first to establish a milk business on these excellent sanitary lines, and we are glad to know that their example has been followed by other great milk companies in London and the provinces.

THE ARMY MEDICAL SERVICE.

As our readers will see by a reference to our Parliamentary Intelligence column Mr. Brodrick declined at the present stage of affairs and under existing circumstances to make any definite statement about the proposed re-organisation of the medical department beyond saying that various measures are in progress to that end. In reply to a question by Captain Norton, as to whether, in view of the fact that there was at the head of the Army Medical Department at the present time only an Acting Director-General shortly about to retire from the service, the Secretary of State for War would say when a new Director-General would be appointed, Mr. Brodrick said: "No, I can make no statement on the subject," accompanying it with a remark to the effect which we have already stated. It is needless to say that this state of uncertainty has a very injurious effect on the medical service and a deterrent influence on any intending medical candidates. There is no end of speculation and conjecture, but nothing is really known as to what are the intentions of the War Office or what is to be the outcome of the present condition of affairs. After what Mr. Brodrick has said on previous occasions there must, we imagine, be a searching inquiry on the part of the Secretary of State into the causes which have led to that condition, the effect of which has been to empty the Army Medical Service of candidates. The sooner this is undertaken the better for all concerned and the promulgation by Mr. Brodrick of the names of those who constitute the committee is anxiously awaited.

ACUTE DERMATITIS FROM A HAIR-DYE CONTAINING HYDROCHLORATE OF PARAPHENYLENE DIAMINE.

In the *Journal of the American Medical Association* of May 18th Dr. A. D. Mewborn has published an important case of acute dermatitis from the use of a hair-dye which is much used in France and which contains hydrochlorate of paraphenylene diamine. A point of particular interest is that the application of this dye to the scalp may produce lesions on distant parts of the skin or even a general eruption. This fact might easily cause the eruption to be overlooked, particularly as patients are prone to deny the use of a hair-dye. A woman, aged 44 years, had severe dermatitis of the face and a pruriginous papulovesicular eruption on the arms and thighs. The forehead was swollen, red, and shiny, and there were a few small vesicles near the margin of the hair. The eyelids, especially the upper, were puffy and the conjunctivæ were slightly congested. The ears were red and swollen; along their upper borders were numerous small vesicles which were filled with straw-coloured fluid and which in places had formed granular crusts. The nose and cheeks were slightly swollen. On the forearms and anterior and inner sides of the thighs were numerous small, mostly perifollicular, papules and a few small vesicles. The patient said that she had had at intervals during the past seven years a somewhat similar eruption which was diagnosed as eczema. The greater intensity of the eruption along the border of the hair and on the upper part of the ears suggested examination of the hair, which showed signs of having been dyed in the temporal and frontal regions. The patient admitted that she had been using a French hair-dye for three weeks. A day or two after commencing its use she felt a prickling sensation in the eyes which was followed by intense inflammation of the face. This dermatitis produced by hair-dye is well known at the Hôpital Saint Louis, Paris. Its zone-like distribution in the upper third of the face, the swollen eyelids, and the vesicles on the margins of the ears are characteristic. Fournier sometimes astonishes a patient by saying: "Madame, you dye your hair; you use a dye composed of two liquids; you apply the dark liquid first and then the clear liquid." Such is the method of applying hydrochlorate of paraphenylene diamine. The first solution is an aqueous or alcoholic solution of the substance; it is applied to the hair on a brush or sponge. The second solution is oxygenated water and is applied a few seconds later on another brush or sponge. The effect is almost instantaneous. Quinone ($C_6H_4O_2$), a substance which gives off irritating fumes, is produced. The hair has at first a violet tint. This becomes darker under the use of the oxygenated water, and tints varying from auburn to jet black may be obtained. The eruption is almost always found on the border of the hair or on the upper lip in those who dye the moustache. The forehead, neck, ears, entire face, shoulders, arms, and even the whole body may be affected. The eruption may appear after the first application or not until the dye has been used for several months. Some subjects have no eruption but complain of prickling in the eyes for days after its use. Intense itching is another characteristic; it may be most marked in the scalp. The eruption consists of erythematous, urticarial, papular, and vesicular lesions. Its involution is slow; the skin remains rough, œdematous, and desquamating for weeks. Brocq has described a grave erysipelatoid form of eruption with fever and adenitis. He saw a young woman who had desquamation of the whole body with great depression and fever. He recommends that in view of the increasing number and severity of the cases a law should be enacted that this dye must be labeled, "Dangerous to persons who have had eczema or who have irritable skins." G. Tissot[1] has arrived at the conclusion that all hair-dyes are dangerous and may produce inflammatory or toxic symptoms, and that their sale should be regulated. Paraphenylene diamine he considers to be the most dangerous. As to the treatment, sedative applications should be used; in the grave forms the hair should be removed, as the dye which remains in it continues to act as an irritant. Of the production of lesions on the body generally several explanations may be given—the transference of the irritant by the hands, the absorption of the drug into the blood, and a nervous influence.

THE HOUSING OF THE WORKING CLASSES.

Salford, like so many other places, feels the difficulty of providing dwellings for working people. The corporation obtained a provisional order some years ago for the demolition of some insanitary property and paid £4 13s. 6d. per square yard for the land. One condition of the order was that provision should be made for the rehousing of the people as soon as possible. The chairman of the Health

---

[1] Thèse de Paris, 1898.

Committee said that if they built four-roomed cottages on the land they would cost between £400 and £600 for land alone, which would mean "a terrible loss to the borough," and if they built four-storeyed tenements there would be a very costly chief rent on each, and he thought that they should try to obtain the sanction of the Local Government Board for leave to sell the land for other purposes. It was objected that in this case over 500 houses had been pulled down and only 61 built to replace them, but in the end the motion was carried that the Local Government Board should be asked to relieve them from the obligation to build on the site of the demolished houses. It is becoming more and more evident that the costly land in large towns cannot be used for workmen's cottages, nor is it desirable on the score of public health that an overcrowded insanitary area should be again overcrowded, the only difference being that in the latter case the tenements are new. Cheap and convenient modes of transit to an outer zone may turn out to be the best solution of the difficulty.

THE NEW CORONER FOR THE CITY OF LONDON.

ON Thursday, June 20th, a meeting of the Court of Common Council was held to elect a coroner in the room of Mr. S. F. Langham who has retired. Out of 18 candidates three had been selected, all of whom were medical men and, in addition, barristers. Their names were: Dr. Major Greenwood; Dr. H. R. Oswald, deputy coroner for the western division of London; and Dr. F. J. Waldo, medical officer of health of St. George-the-Martyr, Southwark, and also to the honourable societies of the Inner and Middle Temples. Dr. Greenwood received 23 votes, Dr. Oswald 52, and Dr. Waldo 96. The Lord Mayor therefore declared Dr. Waldo to be elected coroner. Our views upon the desirability of a coroner being a medical man need no recapitulation here, but we are glad to see that all three selected candidates were medical men. We offer our sympathy to the unsuccessful candidates and our congratulations to Dr. Waldo. He has done such good work in his capacity of medical officer of health of the parish of St. George-the-Martyr that we feel sure that the City has secured an officer in whose hands the honour both of the ancient City and of the ancient office will be absolutely safe.

THE INCREASING PREVALENCE OF CANCER IN THE UNITED STATES.

DR. IRVING PHILLIPS LYON, pathologist to the University of Buffalo, contributes an interesting and somewhat exhaustive study to the June number of the *American Journal of the Medical Sciences* dealing with the increasing prevalence of cancer in the United States, and particularly in the town of Buffalo. A paper by Dr. G. B. Massey on the former subject has been referred to in these columns already.[1] The study of the cancer distribution in Buffalo for the period 1880 to 1899 leads Dr. Lyon to favour the parasitic origin of cancer and to regard it as associated with certain localities, races, and modes of life. Next to direct histological and bacteriological investigation a promising field of research lies, says Dr. Lyon, in the statistical study of the disease in relation to race, social conditions, and natural environment. On a large-scale map of Buffalo all cases of deaths from cancer (2005 in all) were marked out by coloured dots. It quickly appeared that while certain parts of the town showed a scarcity other parts showed a concentration of such "dots" of mortality. "A remarkable concentration is shown in the wards inhabited largely by foreigners, and particularly by Germans." Comparing these facts with the density of the population in order to avoid fallacy, it appeared that nearly every ward in the region showing a concentration of deaths represented "a real and not merely an apparent concentration of cancer." The figures for the period of 19 years (1880 to 1899) showed that German wards with a mean population of 104,753 had 888 cases of death from cancer, while those inhabited largely by native born Americans with a population of 109,527 had 450 cases. The "German" wards include Poles, as the latter came from German Poland and it was found impossible to separate the two races. On the other hand, the Italian quarters, though densely populated, showed a low ratio of cancer mortality. The highest cancer-ratio prevailed among the Irish population—viz., 6 40 times that of the native Americans; then came Germans and Poles, whose ratio was 4 81, while among the Italians it was the lowest of all foreigners—viz., 1 93. In the native-born Americans the male cases of cancer were to the female cases as 50 or 60 to 100. Among the German inhabitants, however, the sexes were affected in nearly equal proportions—viz., 93 males to 100 females, and this applied not only to Buffalo but to the whole of the United States. The Germans and Poles also stood out in contrast with the native-born population, and probably also in contrast with other foreigners, in showing a remarkably high rate of death from cancer of the stomach and liver—viz., 43 8 per cent. of all cancer cases, as against 21 per cent. for the natives. Conversely, a low rate of cancer of the uterus and breast prevailed among German women—viz., 34 4 per cent., as against 61 6 per cent. for females born in the United States. "The lower rate of cancer of the uterus and breast in German than in American women seems," says Dr. Lyon, "to be a weighty argument against the embryonic theory [of cancer], as it is well known that the birth-rate and habit of nursing at the breast are greater among the Germans than the native-born, and therefore, if the embryonic theory were correct, cancer ought to be more frequent in these organs in Germans, because of their relatively greater use and exhaustion. The reverse is shown to be the fact." From a consideration of habits, food, and social environment Dr. Lyon favours the view of infection, mainly from bad food, as a favouring cause of cancer, as upheld by the observations of Behla.[2]

THE DEGRADATION OF THE POST OFFICE.

WE should like to ask His Majesty's Postmaster-General whether something cannot be done to stop the flood of objectionable circulars which are daily and hourly distributed to His Majesty's faithful subjects by means of the department over which he presides. There are the delectable circulars of Mr. Charles Carrington, the swindling notices sent out by Tanqueray, the allurements of money-lenders, and the filthy little books sent out by the blackguard who calls himself Dr. Bell—to say nothing of numerous others. These, however, are sent in closed envelopes and so they may possibly not be recognisable. But there can be no excuse for the distribution of circulars advertising the virtues of various proprietary medicines which mostly emanate from America. Only recently a correspondent sent us a post-card which had been dropped into his letter-box, on which was inscribed a puff of a preparation said to be an absolute cure for painful menstruation, and now several correspondents have forwarded to us the wrappers of circulars dealing with certain pathological conditions and drugs for the same, the said circulars being emblazoned in large letters, "Constipation Number." This sort of thing should be stopped and the Postmaster-General could easily do it if he liked. It is ridiculous to say that officials have not time to investigate. They have time to examine letters and to surcharge them for trivial breaches of the regulations. Only the other day we saw an instance in which a quantity of cards had been sent out. They were all printed with the usual notification of an "At Home," but the date had been filled in in ink. These cards were sent in an open envelope with a halfpenny stamp and had been in many instances surcharged as being of "the nature of a letter." Now, if the Post-office authorities have time to do this sort of thing they could easily detain circulars of the sort to which we have referred. And they will have to do so.

---

THE LONDON HOSPITAL LODGE OF FREEMASONS.

We are glad to be able to announce another recruit to the ranks of Medical Freemasonry, a warrant having been granted by the M.W. Grand Master of the United Grand Lodge of England for the foundation of the London Hospital Lodge. The date of consecration is fixed for Oct. 2nd, at the Hotel Cecil. We believe that the officers named in the warrant are A. E. Sansom, M.D. Lond., F.R.C.P. Lond., as Worshipful Master, and F. S. Eve, F.R.C.S. Eng., and F. J. Smith, M.D. Oxon., F.R.C.P. Lond., as Senior and Junior Wardens respectively. The London Hospital is the sixth metropolitan hospital to attach to itself a Masonic lodge. Freemasons connected with the London Hospital will find further information in our advertising columns.

ORGANISED RESCUE WORK IN COLLIERIES.

A most praiseworthy proposal is receiving, we are glad to learn, very serious consideration by colliery owners. It is the establishment of practical rescue stations in colliery districts. It seems remarkable that such an admirable suggestion has not before been acted upon. We have organisations for the rescue of life at sea, at bathing stations, at rivers, or in the event of fire, but no such organisation has apparently been seriously attempted in colliery districts where too often ghastly losses of life take place. We are sure that if colliery owners could see the benefits to be derived from a local centre from which a body of men could be drawn in case of accident quickly to restore ventilation and afford relief in other matters in connexion with a colliery explosion they would not hesitate to unite in sections and to establish stations throughout the whole of the colliery districts. Dr. J. S. Haldane has clearly shown in his able investigation undertaken for the Home Office that a good deal more might be done towards saving the lives of those struck down by that most poisonous product of explosions in collieries—carbon monoxide. Taking the average of a number of explosions he computed that some 77 per cent. of the men whose lives had been lost might have escaped but for the deadly nature of the after-damp. Undoubtedly, if oxygen could be quickly brought into the mine many lives would be saved, while the rescuing party could, of course, be provided with a means of access and a means also of supporting their own lives during their work of exploration and rescue. Steel cylinders containing compressed oxygen have been suggested for the purpose, and the most recent form of apparatus for breathing in a noxious atmosphere by means of compressed oxygen is the pneumatophore. But, as is pointed out by Mr. M. A. Habershon in a valuable and instructive paper read before the Institution of Mining Engineers, although a number of colliery owners have provided themselves with apparatus comprising one or two pneumatophores it is to be feared that their value in an emergency will be considerably less than it should be because men are not being trained to use them and the apparatus is likely to become only a trap. Again, in order that the pneumatophore may be of real use in any actual work of rescue or exploration it is essential, as Mr. Habershon points out, that there must be at hand without any serious lapse of time, not only a number of these appliances, all of which must be in proper working order, but also an adequate supply of compressed oxygen cylinders, of bottles of caustic soda, and, what is more important still, a number of men experienced in the use of the apparatus. The delay consequent on having to telegraph for, and to await the arrival of, a supply of oxygen would probably render any proposed use of pneumatophores by a rescue party too late to be of any service in saving life and certainly too late for the work of exploration which is generally of immediate importance. A few trained men with pneumatophores and electric lights and a proper reserve supply of oxygen would be able to penetrate any atmosphere, however noxious, and if they could get into the pit during the first few hours after an explosion might obtain information which would be invaluable to those in charge and would facilitate the work of reaching any men who might be shut off from access to the shafts. Of course assistance at the same time could be readily given to any men met with in proximity to the pit bottom. As regards the constitution of rescue corps it is intended at the Normanton collieries to select a number of deputies of workmen from each colliery or pit in the group, only strong, healthy, resolute, and intelligent men who are fit for such work being chosen. Preference will be given to those who are holders of first aid certificates. These men will be required to attend practices or drills with the apparatus at the station until they become sufficiently experienced and obtain the necessary dexterity in the use and handling of the apparatus. A list of the names and addresses of efficient members of the corps will be posted up at the station and will be supplied to each colliery. It is further intended that a sufficient number of the men employed by each of the subscribing companies shall be trained so that eventually each colliery will have a rescue party composed of its own men. We cannot conceive an organisation with a nobler aim than this, and everyone will most heartily wish it God-speed.

DEATH UNDER CHLOROFORM WITH UNUSUAL PHENOMENA.

A somewhat unusual form of circulatory failure following the inhalation of chloroform is reported to us from the Royal Berkshire Hospital. The patient, an anæmic boy, aged eight years, suffering from tuberculous cervical glands, was given chloroform by an accredited officer of the institution with the view of an operation being performed for the removal of the diseased glands. A drop-bottle was employed, the chloroform being dropped upon lint. The quantity used is not known. The patient was nervous and he cried during the administration. At first he dozed off but was aroused and finally was narcotised, the breathing being regular and the pupils contracted. The operation was then commenced. After the skin incision was made and when traction was exerted upon the layer of cervical fascia surrounding the glands the pupils became widely dilated and the respiration grew shallow, although regular and slow, while the pulse was scarcely perceptible. The operation was at once stopped and strychnine was injected, a slight improvement in the pulse taking place. As this was not maintained ether was injected, artificial respiration was commenced, and hot-water bottles were applied, and the boy was removed to the ward. The breathing again improved, a more natural colour appeared, and the pulse grew perceptible. The pupils were now contracted to about normal, the left one (i.e., on the side of the operation) being slightly the smaller. Failure of respiration and circulation again occurred and inflation of the lungs with stimulation by faradaism did not prove successful, the lad dying in about 35 minutes from the first onset of dangerous symptoms. The phenomena detailed certainly appear to have been due to failure of circulation, probably from vaso-motor paresis. It seems likely that during the crying more chloroform was allowed to enter the lungs than the feeble condition of the patient could withstand. As is well known, anæmic subjects are very readily overdosed. The medullary centres, poorly nourished, become narcotised with quantities of the anæsthetic relatively small, while the consequent feebleness of respiration and failure of the vaso-motor safeguard at once lead to accumulation of the poison and deportation of blood from the arterial to the venous system. We do not gather that inversion on the first onset of faintness was put into practice; if it were not it is to be regretted, as we have no doubt that the first remedial measures to be adopted in such cases are inversion and either pulmonary perflation, by preference with oxygen, or, failing this, by artificial respiration. It is very exceptional to find a patient who survives the first few minutes after the dangerous symptoms have arisen is lost eventually, and such an occurrence could only take place as the result of extreme asthenia or very prolonged and excessive narcotisation. It is not unusual in the later stages of the operation for removing tuberculous glands, when traction upon the deeper structures involves interference with the vagus, to find that symptoms arise similar to those reported in this case, although, happily, they are generally relieved by prompt measures.

SAFETY IN NUMBERS?

FOR those people who find pleasure in the manipulation of statistics there is a rich harvest of delight in the recently issued preliminary report and tables resulting from the census investigations of April 1st, 1901. Even the abstract from the report in the *Times* of June 15th is full of figurative plums for that large class of persons who find interest in such matters. It is curious how many men there are to whom bare figures are a source of interest and gratification; men whose chief pleasure in life is the examination of tables, the comparison of annual statistics, and the detection of minor mathematical flaws. To all such the census returns are of course a *bonne bouche*, the taste of which will linger pleasantly for weeks and months of the present year. Even the less statistical, however, can find in these figures something of interest and to the medical man certain facts brought out are not unimportant. He ponders over the astounding increase of town as opposed to country population and on the excess, over 1,000,000, of females over males in Great Britain. Along with the first he places, perhaps, the predominating part that nervous diseases of all kinds tend to acquire in modern nosology and the second makes him introspective of the position of the medical woman. The remedy for such developments of particular kinds of population is, of course, not in the province of medicine. We are engaged in what sometimes appears to be the paradoxical pursuit of preserving human beings, whether fit or unfit, whether their "survival" is really for the benefit of the nation which owns them or the reverse. Healthy or of deficient physical qualities, however, they all play an equal part in the census returns and the most diseased individual may console himself with the reflection that on paper he is as fine an item as Mr. Sandow himself. What is to be done for the female plethora? Physical science offers no resource, for in spite of the sanguine recommendations of certain continental physicians we believe medicine is not yet in a position to offer even the most patriotic of mothers a son when the, at present, inconvertible course of nature has determined on a daughter. The production of women rather than of men is not to be limited by any means at our disposal; it remains for the political forces of society to dispose of them to the greatest advantage for the nation. English women, happily, have never been wanting in the courage and enterprise of their race, and doubtless in our growing colonies will be found the natural home of many females whom it would be ungracious to characterise as "superfluous" in Great Britain.

BRITISH CONGRESS ON TUBERCULOSIS.

WE hear that the arrangements for the above congress are not only in a very forward state in this country but that active measures are being taken abroad to secure a large number of continental visitors. In a previous issue we have given the names of the German committee presided over by His Serene Highness the Duke of Ratibor. In Paris a French committee has been formed under the presidency of Professor Brouardel, with Dr. Thoinot as honorary secretary, assisted by Dr. Morny, Dr. Sersiron, and Dr. Dumarest. This committee has sent out a special circular to members of the profession and others who are particularly interested in the question of tuberculosis. Amongst those who have already inscribed their names are the Prince d'Arenberg, Professor Brouardel, Professor Lannelongue, Professor Proust, and Professor Nocard, and Dr. Martin, Dr. Léon-Petit, Dr. Sabran, Dr. Letulle, and Dr. Hérard. Professor Julian Colleja, President of the next International Congress in Madrid, one of the Vice-Presidents from Spain, is also exerting himself to promote the interests of the cause. Professor von Schrötter, Professor Weichselbaum, and others have likewise joined from Austria; amongst the representatives from America will be Professor Osler and Professor Janeway, while numerous acceptances have been received from Hungary, Italy, Belgium, Norway and Sweden, Holland, Switzerland, Portugal, and Egypt.

FRENCH GOVERNMENT COMPENSATION FOR ACCIDENTS.

AT the International Congress of Miners which met recently in London the British delegates complained that the law on compensation for accident could only be applied if the accident was of so serious a nature that the victim was invalided for more than 15 days. The French delegates, on their side, complained that the French law only allowed compensation on the fifth day, and though this was a great improvement on the English law, still they were not satisfied. The French Government apparently shares this dissatisfaction, and it is in this respect ahead of the French legislature. On Feb. 1st, 1901, an official circular was issued in regard to the compensation to be paid to workmen in Government employment when they were injured in the course of their work. This circular points out that, according to the law of April 9th, 1898, a workman temporarily incapacitated through an accident was entitled to receive half the wage he was earning at the time when the accident occurred if on the fifth day he was not able to return to work. But before this law was enacted Article 20 of the decree of June 1st, 1875, had stipulated that workmen in Government employ who fell ill or met with an accident and were confined to their beds were from the first day to receive their full wages for, however, not more than three months. If the illness or accident was so serious that the patient did not recover in the course of three months then a special arrangement would be made. The circular of Feb. 1st, 1901, explains that if the Government were to content itself with the application of the Law of 1898 the position of the workers in their employ would be much less favourable than formerly. Therefore the circular calls attention to the Ministerial decree of Jan. 23rd, 1901, which states that an accident causing death or permanent, complete, or partial incapacity from work shall be dealt with according to the law of April 9th, 1898. But the law shall only come into operation after the tribunals have recognised the permanent character of the incapacity resulting from the accident. Till such time and even if it extends beyond the three months' limit established by the decree of 1875, the workman shall receive from the State his full wages. If, however, the injured workman is not nursed in his own home but is treated and maintained in a hospital he will still receive half his wages, so that his family shall not be in distress. In a word, the principle is full wages or the equivalent in hospital treatment till the workman is cured and returns to his work, or, being recognised as permanently injured, is pensioned off. Thus the Government seeks to set an example as a model employer. Its generosity goes far beyond the stipulations of the law.

DEATHS FROM ANTHRAX.

THE comparative rarity, happily, of deaths from anthrax renders the two fatal cases that recently occurred in Bradford the more noticeable. Anthrax, or wool-sorters' disease, is pre-eminently one in which thorough precautions taken for and by those whose work exposes them to contamination will go far towards ensuring perfect safety. Absolute safety is of course not merely a matter of providing the means for obtaining it. A large part depends in this, and in all similar circumstances, upon the care and intelligence with which a workman uses the weapons of defence that are placed at his disposal. Unfortunately the familiarity of contempt is rapidly bred among workmen, and employers often suffer, not because they have not as far as possible made every provision for the safety of their men, but because the men have grown careless in using such provision. In the first of the two cases to which we are referring some such state of affairs may be responsible for the death. At any rate, it appeared in the evidence at the coroner's inquest that all the factory regulations had been complied with, that wool was sorted only over a sorting board, and that employés were forbidden to take food in the carding-room. In spite of these precautions a "card-feeder" had developed a malignant pustule on the back, from which she died in a few days. The second case was that of a man who, it seemed fairly obvious, had contracted the disease through sorting dangerous wools in a cellar, without any precautions being taken. He contracted anthrax of the face which rapidly proved fatal. Evidence showed that the wool-combers' business where he was employed was old-fashioned and that modern methods were only being gradually introduced. A verdict of manslaughter was returned against the manager.

THE CERTIFYING OF LUNATICS.

IN consequence of several recent scandals connected with certain Poor-law unions in which the relieving officers have received payments from the district medical officers or from proprietors of private asylums and licensed houses in connexion with the certifying of lunatics and their admission into such houses, a circular letter has been addressed from the Home Office to clerks to county and borough justices, stipendiary magistrates, and the metropolitan magistrates, drawing attention to the following points: 1. Section 16 of the Lunacy Act, 1890, directs that in the case of a pauper lunatic who is brought before a justice the latter "shall call in a medical practitioner and shall examine the alleged lunatic," *and it is only when the practitioner has signed* a medical certificate with regard to the lunatic that the order for his removal can be made. In some cases relieving officers have usurped the duty of selecting the medical practitioner, a proceeding which not only violates the law but has lent itself to grave abuse. 2 A justice should not sign the reception order until the medical certificate has been signed and laid before him. In some cases a laxity has been noted in this respect. 3. The name of the institution to which the lunatic is to be removed should be filled in by the magistrate or justice and not left blank. The latter course has permitted relieving officers to fill in the blank with the name of any institution to which they had inducements to take the patient and it has been also advised by the law officers of the Crown that if the blank is not duly filled up the order cannot be legally acted on. 4. Finally, according to Section 27, Sub-section 2, of the Act the lunatic "shall not be sent elsewhere than to an asylum of the county or borough in which the place from which he is sent is situate," except owing to absence of accommodation or special circumstances. Magistrates should be specially insistent on the observation of this rule as far as practicable. These instructions are both necessary and opportune just now.

ANEURYSM OF MYCOTIC-EMBOLIC ORIGIN.

DR. O. LING of Dorpat contributes to Part 5, vol. ix., of the *Russky Archiv* (edited by Professor Podwissotzky of Kieff) an article on Aneurysm of Mycotic-embolic Origin. It is a paper of considerable interest, both from a practical and theoretical point of view, inasmuch as it deals with a comparatively rare affection, the pathology of which has as yet received but little attention. Up to the present time not more than some ten cases—exclusive of the one which Dr. Ling reports—have been described in which the real nature of the malady was recognised during life. Dr. Ling begins by analysing the literature of the subject, paying particular attention to Eppinger's observations and conclusions as laid down in an exhaustive monograph by the latter observer. He then proceeds to relate the case of his patient. A lad, 19 years of age, was admitted to the hospital suffering from a complex of symptoms characteristic of so-called "crypto-genetic septopyæmia and septic endocarditis." It appears that on the seventh day of his illness he was suddenly awakened in the morning by intense pain located in the bend of the left elbow, though on examination nothing abnormal could be detected. Soon, however, one important symptom made its appearance—namely, the absence of pulsation in the left ulnar artery and, in addition, it was noted that the pulsations of the left radial artery were of a greater number and more intense in character than those of the right one. In the further course of the disease a comparatively large pulsating tumour, which ultimately became distinctly obvious, was discovered at the very point where the original pains were situated and there were also present a slight but marked swelling of the surrounding parts and discolouration of the skin. The formation of the aneurysm was attributed to a septic embolus which originated in one of the diseased heart valves and located itself at the point of division of the brachial artery into the radial and ulnar branches, thus causing a permanent obstruction to the circulation in the latter and subsequently leading both to the destruction of the arterial coats and the formation of the pseudo-aneurysm. The presence of continued fever throughout the course of the disease is recorded by Dr. Ling as one of the most striking features of the affection. The fever was irregular, presenting at one time the remittent and at another the intermittent type. There was hæmaturia. The condition of the patient gradually became worse, general cachexia and complete collapse soon ensued, and he died seven weeks after admission to the hospital. Dr. Ling gives a minute description of the pathological changes which were found on post-mortem examination. There was an ulcerative endocarditis, partly of an acute character and mainly confined to the mitral and aortic valves; the spleen presented numerous infarcts which were well defined and differed from each other as regards size and appearance; and both kidneys were found to be in an acute hæmorrhagic state. The coats of the thoracic and abdominal aorta were found unaltered. As regards the nature of the tumour of the left elbow it was found that its coverings consisted of thick membranous layers of newly-formed tissue, thus producing a cavity which was filled with both coagulated blood and puriform matter. The aneurysm contained numerous micro-organisms, practically identical in every respect with those cultivated by Dr. Ling from the mitral and aortic valves of the patient.

PLAGUE IN CAPE COLONY.

A TELEGRAM received at the Colonial Office on June 20th, gives the following statistics of plague at Cape Town for the week ending June 15th. Fresh cases: Europeans, 3; coloured persons, 4; Malays, Indians, Chinese, and natives, 0; total, 7. Corpses found: Europeans, 1; coloured persons, 5; Malays, 1; Indians, Chinese, and natives, 0; total, 7. Deaths (including corpses found): Europeans, 2; coloured persons, 7; Malays, 3; Indians and Chinese, 0; natives, 1; total, 13. The total cases up to June 15th have been: Europeans, 186; coloured persons, 327; Malays, 54; Indians, 11; Chinese, 2; natives, 145; total, 725. The total deaths have been: Europeans, 52; coloured persons, 170; Malays, 39; Indians, 9; Chinese, 0; natives, 64, total, 334. One case, that of a private in the 1st Battalion Welsh Regiment, has occurred among persons under naval and military control. The total cases to June 15th amount to 50, including 10 deaths. At Port Elizabeth for the week ending June 15th the cases of plague have been as follows: Europeans, 1; Chinese, 1; natives, 2; total, 4 One native died. The cases to June 15th have been: Europeans, 2; coloured persons, 2; Chinese, 1; natives, 6; total 11. Total deaths: Europeans, 1; coloured persons, 2; natives, 3; total, 6 The total cases at Mafeking to June 15th have been: Europeans, 2—both privates in 1st Battalion Loyal North Lancashire Regiment. The area of infection remains unchanged.

THE DANGERS OF CHEMICALS IN TRANSIT.

WE have more than once referred to the increased traffic in chemicals and to the new dangers which thereby arise in connexion with those concerned with the transit of such substances. Liquid gases are now a commercial commodity, and to such an extent that special legislation was needed to provide for their safe transportation. Even the cartage of these things through the streets is not without risk to the public. On board ship all kinds of chemicals are carried—metallic sodium, caustic soda, sulphuric anhydride, sulphurous acid, liquid carbolic acid, naphtha, nitro compounds, chlorates, and many other substances with ugly potentialities. In bad weather packages may get adrift and be smashed and the contents may not only damage the ship but be a menace to crew and passengers. It has happened in this way that different chemicals have got mixed, with the result that violent explosions have ensued or poisonous fumes have been produced and the crew overpowered. It is evident, therefore, that the greatest care should be taken as to how such goods are stowed, having regard to the possibility of bad weather and the rolling of the ship, in order that the danger and risk to life may be minimised. The crew, as a rule, are ignorant of the destructive or corrosive nature of the chemical cargo which the ship may be carrying. Such would appear to have been the case in an accident reported recently, although it must be admitted that the circumstances in this case are exceptional and the fatalities which happened are involved in some mystery. A ship sailed from Liverpool to Rotterdam with, amongst other things, a cargo of 48 barrels of crude carbolic acid in hard-wood oil-casks. At sea in rough weather the barrels broke adrift and got smashed, the acid contents being nearly two feet deep in the compartment. Three of the crew went to secure the casks but were badly burned, overcome by the acid, and died almost immediately. At the inquest the deaths of the three men were attributed to the fumes of the acid, but, as Dr. Dupré pointed out in the Board of Trade investigation, death could not have resulted from fumes, because at an ordinary temperature the acid would not give off any appreciable vapour at all. Death was probably partly the result of shock resulting from acute burns and partly due to the absorption of the acid through the skin. The suddenness of the deaths is remarkable. Cases, however, have been recorded in which the external application of carbolic acid resulted in sudden death as though prussic acid had been taken. Instances are, of course, known in which carbolic acid poisoning followed the external application of the acid. It has happened, for example, when the acid has been used prior to a surgical operation. It seems to us that special regulations are needed which will offer greater protection to those who may have to deal with cargoes of chemical substances. The usual ship gang do not understand the dangerous nature of some of the goods which they handle and we consider that when special cargoes of this kind are taken on board warnings should be issued to the crew that they must be on their guard in the event of an accident occurring in the way just described.

STALE v. NEW BREAD.

NEW bread is well known to be less digestible than stale bread, although it need not be so. There can be no question, however, of the vastly superior flavour of the former, and hence the preference of many people for hot rolls for breakfast. So far the palate would appear not to be a safe guide to digestion. Hot rolls, however, when masticated properly should not offer any difficulty to the digestive organs. A slice of stale bread on being broken with the teeth resolves into more or less hard gritty particles which unless they were softened by the saliva would be almost impossible to swallow. The particles would irritate the throat and the gullet. The fact is, therefore, that man is compelled thoroughly to masticate and to impregnate stale bread with saliva before he swallows it. This act, of course, partially digests the bread and thus makes it in a fit state for digestion and absorption farther on in the alimentary tract. This is why stale bread appears to be more digestible than new bread. New bread, on the contrary, is soft, doughy, or plastic, and there appears to be no necessity to soften it with saliva, hence it escapes the preliminary digestive action of the ptyalin of the saliva. New bread, in other words, is in reality "bolted," and "bolting" accounts for many of the ills arising from dyspepsia. Accordingly, hot rolls should be enjoyed for breakfast without any fear of dyspepsia so long as the bread is good and so long as pains are taken to masticate it thoroughly. When a dog is given a piece of meat it will be noticed that he "bolts" it. There is not much reason why it should stay in the mouth, for the mouth, beyond reducing it by the aid of the teeth to a convenient mass, cannot deal with its digestion; but if the dog be given a piece of bread, supposing he eats it at all he will keep it in his mouth for some time and will almost labour over it before swallowing it. The dog thus teaches a very important physiological lesson. It is a curious fact that stale bread is not more dry than new bread, for on submitting stale bread for a short time to a high temperature it regains its condition of newness and becomes soft or plastic and this in spite of the fact that some moisture is of necessity driven off in the operation. It is probable that in new bread there is free water present while in stale bread the water is still there but in a condition of true chemical combination, and it is this combination which compels us thoroughly to moisten and to masticate stale bread before we consign it to the gastric centres. Similarly the indigestibility of the Norfolk dumpling is probably due to the fact that it is of tough doughy consistency and therefore should receive considerable mastication before it is swallowed. It is a sound physiological plan, therefore, to adopt—as it is said the late Mr. Gladstone adopted—the habit of chewing each morsel a great number of times.

THE SYMPTOMS OF TUMOURS OF THE FRONTAL LOBE OF THE BRAIN.

DR. HONIGER records in the *Munchener Medicinische Wochenschrift* of May 7th the symptoms and diagnosis of cerebral tumours affecting the frontal lobe. The tumour may be situated in the region extending from the frontal pole to the anterior or ascending frontal convolution on the convex surface and on the basal surface from the frontal pole to the posterior limit of the roof of the orbit. A diagnosis of frontal tumour may be made when it is accompanied by disturbance of the psychical functions (*Seelenleben*). When lesions of the frontal lobe in the form of atrophy, as in certain idiots, or of diffuse encephalitis or paralytic insanity result there is produced a marked impairment of intelligence. The mental alteration may express itself in the form of loquacity and a tendency to joking combined, and this condition of irrepressible quibbling (*Witzelsucht*) is especially marked when the left frontal lobe is the seat of the tumour. One such case was that of a woman, 50 years of age, one year after she had attained her menopause, and she developed melancholia with hypochondriacal delusions of unworthiness and suicidal desires. There was slight facial paresis on the left side, but there was no appearance of "choked disc" on ophthalmoscopic examination. The above form of loquacity was present. She gradually grew demented and died in a condition of apathy. The occurrence of the above peculiar disposition towards speech was of diagnostic and localising importance, and though but little known is referred to by Bruns in his important work on cerebral tumours. Another trait is an ataxic condition of gait which resembles that of a drunken person. Usually there is not any alteration of reflexes or of sensibility. The abnormal stumbling gait is attributable to a weakness or paresis of the trunk muscles in the lumbo-sacral region and sometimes to a spasmodic contraction of these muscles. A permanent paralysis of these muscles follows as the tumour grows and enlarges, involving the cortex of the superior frontal convolution. In proportion as the tumour approaches the third frontal convolution (Broca's speech-centre) on the left side speech disturbances predominate. Other symptoms develop if the tumour approaches the so-called "motor" area. When the tumour starts in the basal or orbital aspect of the frontal lobe its proximity to the olfactory and optic nerves may give rise to symptoms of disturbance of those nerves. The paralysis of the lumbo-sacral muscles (rump-muscles) has been correlated by Wernicke with the characteristic disturbance of gait, and Munk by experimental ablation of the frontal lobes in both dogs and monkeys has produced analogous results. Hitzig in his earlier experiments had already shown that movements of the rump-muscles were represented in the lateral portion of the gyrus cruciatus in the cat and the dog. A case is given where the diagnosis of frontal tumour was made on the basis of paresis of the rump-muscles associated with sacral pain in a man, aged 54 years. There was the characteristic disturbance of gait, and the symptoms pointed to involvement of the right frontal lobe. Later he developed local headache and tenderness over the site of the tumour, and there were symptoms of pressure on the arm area, producing paresis of the left arm. A few hours before death the temperature rose in the axilla to the extraordinary height of 41·5° C. (106·7° F.). The necropsy revealed an enormous tumour involving nearly the whole of the dorsal half of the frontal lobe, and extending from the frontal pole backwards as far as the fore-edge of the ascending frontal convolution.

MACCLESFIELD GENERAL INFIRMARY.

IN consequence of the resignations from the honorary medical staff of Mr. J. Somerville and Mr. J. B. Hughes, his juniors, Dr. J. L. Rushton has also recently resigned his position among the active medical officers of the Macclesfield General Infirmary. The three oldest members of the staff have thus severed themselves from a position which they have held for many years with credit to themselves and with advantage to the institution. They had been on the staff of the infirmary since it was first opened. If at the monthly meeting of governors at which these resignations were formally announced it seemed right to the chairman to add any expressions of opinion or sentiment upon the withdrawal of these senior medical officers, we should have expected gratitude more than any other feeling to predominate in his remarks. The chairman on this occasion, however, thought fit to expatiate rather on the advantage of securing the services of younger and "more up-to-date" practitioners—a singularly ungraceful way of bidding farewell to gentlemen who had for many years given gratuitously a large part of their time to the welfare of the institution which they were leaving. That the chairman's predominating sentiment was not the feeling uppermost in the minds of the rest of the governors was shown by Mr. Alderman Pickford, who, in proposing that the resignations should be accepted, remarked that they felt they would be conferring an honour upon themselves as well as upon Dr. Rushton if they appointed him on the honorary consulting staff of the institution.

STREET NOISES.

THE flat-racing season is now in full swing and the "runner" is accordingly more of a nuisance than ever. As we have said before, the police decline, as a rule, to interfere except upon the personal complaint of an annoyed brain-worker. This conduct renders the by-law of the London County Council perfectly useless, though in the circular originally issued by Sir Edward Bradford it was implied, if not explicitly stated, that the police could act upon their own initiative. We quoted in a previous number a case in which a constable did act upon his own initiative and where he was backed by the magistrate.[1] But at present the by-law is a dead letter, and we can only urge everyone who is annoyed by "runners"—and that class will include most people—that the best way of obtaining redress is to bombard the member of the County Council for the division in which he resides with letters concerning the nuisance, letters which will ask that he should bring the matter again before the Council. The Council, we hope, will, if worried enough, again call the attention of the police to the by-law and thus the nuisance may be stopped. This should be done in all parts of London, but for ourselves we hope that a commencement will be made with the Strand. If the big business firms, the hotels, the banks, and the newspaper offices all complain there is a fair hope of relief. In the meantime we would point out that even when a citizen does take the trouble to appear at a police-court certain magistrates give him practically no redress. At the City summons police-court Mr. Alfred Moore appeared to complain against a newsboy for shouting. Sir Horatio Davies is reported as having said: "People have to pay very high rents in the City and should be protected against a nuisance of this kind, but the public would be very much inconvenienced by not being able to get their evening papers." Mr. Moore remarked that they could see if they did not hear, whereupon the magistrate said: "No one would know much about them being there if they did not call out." The fatuity of this remark is amazing. There are numbers of newsvendors who do not shout and who yet can sell their papers. The boy was fined 6*d*.!

---

[1] THE LANCET, July 14th, 1900, p. 120.

NOTIFICATION OF PULMONARY TUBERCULOSIS.

EVERY step that helps to impress upon the general public a knowledge of the extent to which pulmonary tuberculosis is an infectious and preventable disease must be a step in the right direction towards diminishing the, at present, terrible mortality from tuberculosis. On these grounds the notification of pulmonary tuberculosis may be regarded as a beneficial innovation. Notification, compulsory or voluntary, has not, however, yet been long enough in vogue even in those parts of America where we believe it was first practised for definite conclusions to be drawn as to its value in diminishing the disorder. Moreover, there are certain difficulties that must be recognised with regard to compulsory notification. The first rural district council to institute voluntary notification of pulmonary tuberculosis—that of Bucklow—has recently issued a notice to the medical men within its region of influence A fee of 2*s*. 6*d*. is to be paid for each voluntary notification, and bacteriological aid to diagnosis is obtainable from Mr. T. W. H. Garstang, the medical officer of health, when desired. We have no doubt that the Bucklow Rural District Council is taking a step likely to be approved by the medical men of the neighbourhood and imitated by district councils elsewhere.

THE introductory address at St. George's Hospital, on Oct. 1st, will this year be delivered by Dr. P. W. Latham, of Cambridge. Mr. J. Warrington Haward will preside over the annual dinner in the evening. The Lord Chief Justice of England has consented to preside at the annual distribution of prizes in October.

THE Committee of Management of the Royal Orthopædic Hospital have been informed through the Earl of Denbigh, the President of the hospital, that Queen Alexandra has graciously acceded to the request made to Her Majesty to become patroness of the charity, in succession to her late Majesty Queen Victoria.

THE summer meeting of the Anatomical Society of Great Britain and Ireland will be held in the Medical Department of the Yorkshire College, Leeds, on Friday, July 5th, from 2 to 5 P.M., and on Saturday, July 6th, from 10 to 12 30 A M

THE twenty-eighth festival dinner of the Royal Medical Benevolent College will be held at the Hotel Cecil on Tuesday, July 9th, at 6 30 for 7 P.M. The chair will be taken by the Right Honourable the Earl of Rosebery, K G.

THE new Pathological Institute of the London Hospital will be opened by Sir Henry Roscoe, D.C.L., F.R S, on Wednesday, July 10th, at 3 P M. The distribution of prizes by Sir Henry Roscoe will take place on the same day.

DR. F. W. HEWITT has been appointed Emeritus Lecturer on Anæsthetics and consulting anæsthetist at the London Hospital on his resignation of the post of instructor in anæsthetics which he has held for 15 years.

HIS MAJESTY THE KING has graciously consented to become patron of the Surgical Aid Society.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on June 20th, Sir WILLIAM MAC CORMAC, Bart, K.C.B., K.C V.O, the President, being in the chair.

The PRESIDENT reported the attendance of the delegates of the College—namely, the President, the Senior Vice-President, and Professor Mayo Robson—at the Ninth Jubilee Celebrations of the University of Glasgow and the presentation by them, on behalf of the Council, of an address of congratulation.

A complaint was received from the Medical Defence Union of the conduct of a Member of the College in associating himself with the publication of two pamphlets by means of which it was thought that the Member advertised. The Council, on the recommendation of the Discipline Committee, decided to request the Member to furnish the Council before their next meeting with any explanation that he might desire to offer.

The following examiners were appointed for the ensuing year:—

BOARD OF EXAMINERS IN ANATOMY AND PHYSIOLOGY FOR THE FELLOWSHIP

Anatomy—James Ernest Lane, Frederick Gymer Parsons, Alfred [illegible] Thompson, Thomas [illegible]

CONJOINT EXAMINING BOARD

First Examination.—Elementary Biology—Frederick Gymer Parsons, Herbert Willoughby Lyle, Peter Chalmers Mitchell, and Walter G Ridewood.

Second Examination—*Anatomy*—William Bruce Clarke, Stanley Boyd, Arthur Robinson, and Arthur Thomson—*Physiology*—Leonard Erskine Hill, George Alfred Buckmaster, and Ernest Henry Starling

Third Examination.—Midwifery—Herbert Ritchie Spencer, William Radford Dakin, William Duncan, and James Henry Targett

Examination in Public Health—*Part I*—Alexander G R. Foulerton. *Part II*—S A. Monckton Copeman

The Council accepted with thanks the offer from Mr. Algernon Tatham to present to the College a silver medal awarded to the late Sir Erasmus Wilson by the Royal Humane Society for saving a young woman from drowning in 1857.

The Council confirmed the following standing rules for the awarding of the Cartwright prize:—

1. The Cartwright prize will be awarded quinquennially and the first award will be for the five years ending Dec. 31st, 1905

2. The prize consists of a medal executed in bronze and an honorarium of £50

3 The subject for the essays to be submitted in competition for the prize is "The Surgical Diseases having their Origin in Abnormal or Diseased Conditions of the Teeth and their Structures, the essay to be illustrated by pathological and microscopical specimens."

4 Candidates for the prize must be persons engaged in the study [illegible]

6. Every essay must have a motto or device and must be accompanied by a sealed paper containing the name and address of the author, and having on the outside a motto or device corresponding with the motto or device on the essay

7 Each essay must be addressed to the Secretary of the Royal College of Surgeons of England and delivered at the College not later than 4 o'clock P M. on Dec. 31st, 1905

8. The manuscript prize essay and every accompanying drawing and preparation will become the property of the Royal College of Surgeons of England.

9 Every unapproved essay which is unclaimed at the expiration of 12 months from the date of its receipt will be returned, with any accompanying drawing and preparation, to the author thereof at the address given in the sealed envelope.

INVALID RAILWAY TRAVEL.

BY E. M. CORNER, F.R.C.S.ENG., B.SC.LOND., M.D.CAMB.,
RESIDENT ASSISTANT SURGEON AT ST. THOMAS'S HOSPITAL.

THE subject of invalid railway travel must often be brought to the mind of practitioners, yet there is no succinct form in which knowledge of the subject can be obtained. Many people are also interested in railway matters but in the course of a busy life have neither time nor opportunity to cull knowledge for themselves. Invalid travel and accommodation is a subject which is of interest to both patients and railway companies as well as to the practitioner and therefore deserves attention from the profession. As in so many other things, luxury is only to be bought, and consequently the comforts of travel can only be enjoyed by those who are able to pay well for them. The time and the amount of such traffic have not yet come when the various companies can charge less than first-class fares; and, again, as yet there is no competition.

The lines of railway which extend along the southern, and especially the south-western, coasts are those which must naturally have the greatest amount of such traffic and they are the lines that cater most for it. Any line which has a terminus in London must be called upon sometimes to convey invalids to it, and the same remark will apply in a lesser degree to all large towns. The great northern railways do some considerable traffic in this way as well as in bringing invalids down to, or near, London in order that they may continue their journey to their destination elsewhere. To allow of invalids suffering the least possible disturbance they can be carried from place to place over several companies' lines and never be moved from the saloon in which they travel. Arrangements will be made for them in advance and the lump sum paid will be divided amongst the various companies at the Railway Clearing House. Hence the only condition that is requisite is that the lines should be of the same gauge, which is standardised at 4 feet 8½ inches throughout all the great lines of the British Isles. This complete system of transference from line to line without any extra trouble or payment on the part of the traveller is an inestimable boon. When travelling by invalid saloon or family saloon the patient will be taken by fast trains, but with the "crack" trains that are timed closely and run fast the companies may object to the extra weight. But as a rule these scruples can be overcome. When travelling by the invalid road car on a truck, it will not be hooked on to the first-class trains. This is not only for the look of the thing, but also because the truck may interrupt the continuity of the break with the carriages behind it and with the engine.

The situation in the train selected for the invalid's carriage is at the middle where oscillation is least. On a few lines, such as the London, Brighton, and South Coast Railway, where the train is split into two portions—the London Bridge and the Victoria—at Croydon, the carriage is apt to be brought the remainder of the journey very close to either end of the train.

The greatest achievement in invalid travel has been accomplished recently by the London and South-Western Railway when they constructed their hospital train for the use of the wounded returning from the war. It consists of five carriages 48 feet long, run on bogies, splendidly constructed and equipped. They represent the acme of comfort, but they are made to carry many and not a single invalid. The Great Western Railway offer the largest and finest invalid saloons with all the most modern improvements. Of lines on which the invalid traffic is less the London and North-Western Railway and the Caledonian Railway stand out distinct in offering to invalids a temporary modification of their splendid family saloons.

The various methods of invalid travel are by the invalid saloon or railway carriage, the modified family carriage or saloon, reserved compartments and seats, and the invalid road carriage, all of which will be considered categorically and the expenses incurred by each method will be stated.

THE INVALID SALOON.

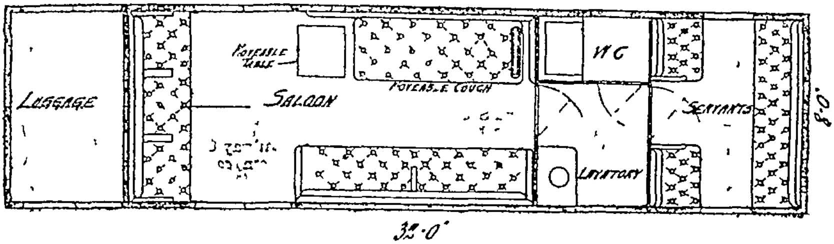
All the great railways build some special coaches, called invalid saloons or railway carriages (Figs. 1 and 1A), which represent their chief effort to meet the requirements of this class of passenger. The saloons are usually divided into four compartments—one for the invalid, one for the attendants, one for the luggage, and one to be used as a lavatory; and these supply all the room and comfort which an invalid needs when travelling. In length the carriages vary from 30 to 34 feet and they run upon six wheels. Only one company has an invalid coach running upon bogies and the long and luxurious carriages of the best trains contain too much room and have too much unnecessary weight to be built for invalid saloons. Hence the shorter and older type of six-wheeled coach is adopted by all the railways, with one exception—the Great Western. The length of the compartment for the patient varies with the length of the carriage, usually from 17 feet to 19 feet and it usually contains a special couch which differs in some points with the various companies and carriages. The couch may be fixed or moveable, slung by special springs from the roof, &c. On some lines hooks are put in the roof so that a special mattress or hammock may be slung—such a carriage must be specially asked for as the generality of the invalid stock has no such requirement. Special straps anchor the mattress to the floor, limiting the oscillation. On certain lines the couch can be lifted and used as a stretcher to convey the invalid in and out of the saloon. When the couch is thus moveable it can be readily replaced by a bed which forms part of the regular furniture of an invalid saloon only upon the Great Central Railway. Many other lines—such as the Midland, the London and North-Western, the Great Western, the Great Southern and Western of Ireland, and others—will supply a bed where it is required. The Midland, the Great Western, and the South-Eastern and Chatham railways have their invalid couches slung by spiral springs from the roof and their movements restrained by leather straps (Figs. 2 and 3). Otherwise this arrangement, if it is required, must be specially asked for.

The doors of the saloon are usually of double width to enable the patient to be carried in or out upon the couch on which he has been brought to the station, so that he can either continue the journey on the same couch or be transferred to the couch in the saloon. By the first of these arrangements the least possible disturbance of the patient is necessary, as he need never be moved from his couch from the time of his departure till he arrives at his destination.

Besides the couch for the invalid another couch is sometimes present and is placed upon the opposite side of the carriage to that on which the former is placed. Three or four comfortable chairs are placed for the friends of the patient, of which some are fixed and some are moveable. Occasionally an invalid chair is supplied on which the patient can be wheeled about the compartment, such as to and from the lavatory. An invalid bed-table is sometimes provided. The saloon is well lighted by large windows, is well ventilated, and is upholstered in a style that leaves little to be desired. The carriages are warmed either by steam from the engine or by means of foot-warmers, the proper temperature being obtained in the carriage before the arrival of the patient. The latter method is the one most usually employed. The Midland and Great Western railways alone have any arrangement for the warming of food, &c., supplied in the carriage, a Bunsen stove being provided. Such an apparatus could be easily fitted on to the jet of any carriage lighted by gas, otherwise the attendants will have to bring their own apparatus. The Great Eastern Railway add a fifth compartment to their invalid carriage, which seats four friends and communicates directly with the patient's saloon. The composite invalid saloons of the Great Northern Railway, besides the ordinary four compartments for the invalid, the attendants, the luggage, and the lavatory, have an additional third-class compartment between the invalid and the luggage locker, which is isolated from the rest of the carriage.

The attendants' room is usually a second-class or third-class compartment which is connected by doors with the rest of the carriage, and is usually separated by another compartment from that of the invalid, and which is generally the luggage-van or the lavatory, but which of these it is varies considerably with the different lines. In the majority it is the lavatory, which may be entered through the doors from either the patient's room or the attendants' compartment. In this situation the lavatory may be used by all. The London and South-Western Railway are peculiar in placing the lavatory at the end of the carriage next the invalid (Fig. 4), giving a comparatively large compartment, 3 feet 7 inches in breadth, as compared with 2 feet 9 inches, with the water-closet on one

FIG. 1.



Invalid Saloon, Midland Railway, showing ordinary constitution and disposition of luggage locker and lavatory.

side of the carriage and a washing-basin on the other; but as a general rule the lavatory is, as we have said, between the attendants' and the invalid's compartments, whilst the luggage is placed at the end. This form is the most comfortable for all parties. The other will be most appreciated by the invalid and may be the more satisfactory upon long journeys.

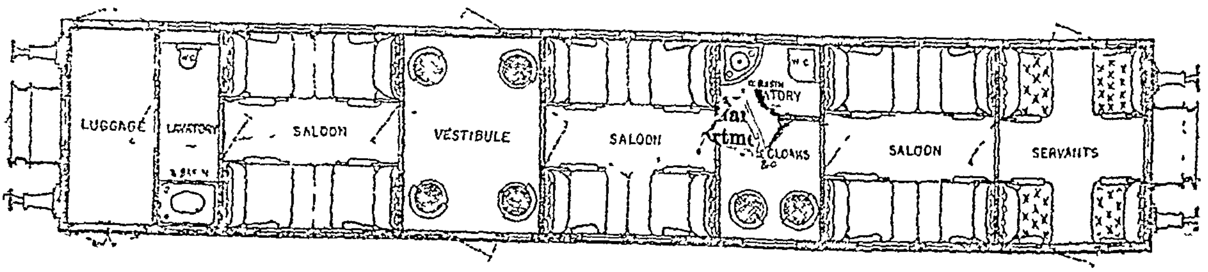
The Great Western Railway have an invalid traffic as large as, if not larger than, that of the London and South-Western line. They offer to the public the finest and most modern invalid vehicle, which deserves a special description. The carriage is 46½ feet long and runs upon two four-wheeled frames which can rotate under the carriage, thus diminishing all jolting, &c. These frames are called "bogies." At one end is a compartment 18 feet long with a couch for the invalid specially slung upon springs and anchored to the floor; next to this comes a lavatory, 5 feet 9 inches long and 3 feet 7 inches wide, and then follow two compartments for friends and attendants, the final division of the carriage being a luggage locker. A passage runs down one side of the carriage. This carriage can be hooked on to a corridor train. These saloons are modifications of the family carriage and lead on naturally to the next division of this report.

The price charged for the use of an invalid saloon on the various lines is as follows. On the Great Central, the North-Eastern, the London and North-Western, the Midland, the Great Northern, the Caledonian, the Glasgow and South-Western, and the North British railways, four first-class and four third-class fares. It will be noticed, however, that there is a regulation clearance office charge which is the same for all these northern railways. On the Great Eastern and Great Western railways the charge is seven first-class fares; while on the Great Southern and Western Railway of Ireland, the Great Northern Railway of Ireland, and the London and South-Western Railway it is six first-class fares. The South-Eastern and Chatham Railway charge 1*s.* per mile with a minimum charge of 40*s.*, while on the London, Brighton, and South Coast line the rate is 9*d.* a mile with a minimum of 40*s.* The above prices represent the minimum charge and all passengers must pay first-class fares except servants who pay third.

THE FAMILY SALOON.

The managers of lines which have no special invalid rolling-stock, and of some of those which have, advise the use of a family saloon for invalids to travel in. On the big lines these carriages represent the acme of comfort that the railway companies can offer. The family saloon is much longer than the invalid saloon, ranging from 42 feet to 48 feet in length, it is much heavier, and is run upon four-wheeled bogies. A bogie is a framework with wheels upon which the carriages can move, thus diminishing jolts, &c., and adding greatly to the smooth running of the coach. There are three separate compartments containing four seats each. At one end of the carriage is a luggage-van and next to it is a comfortable lavatory about three feet in breadth. The compartment which follows is that which is best transformed, with bed or couch, for the invalid's use; it is eight feet long, just allowing room for a comfortable couch to be made up Next the invalid's compartment is a vestibule containing four seats, followed by two saloons similar to the above and separated from each other by a second vestibule with a lavatory in it. The end compartment is for the servants (Fig. 5).

FIG. 5.



Family Saloon, London and North-Western Railway.

This variety of coach is of special value for long journeys on account of its smooth running, its equable temperature, which is obtained by steam heat from the engine, and its special lavatory for the invalid and a second one for others.

It can also be attached to the corridor train and so enable the passengers to communicate with the dining-car, but it must then be placed at one or other end of the train to avoid its being used as a passage by other people. A few of these cars contain a small stove which might be utilised for heating food, &c. The price for such a coach is the same as that for an invalid saloon—viz., usually four first-class and four third-class fares—and in it the London and North-Western Railway can take a patient from Torquay to the north of Scotland.

The Caledonian Railway Company offer invalid stock like that of their southern *confrère*, the London and North-Western Railway.

RESERVATION AND ALTERATION OF COMPARTMENTS.

On most lines less expensive modes of travel can be obtained, such as the engaging of a first-class or third-class carriage, which can then be made suitable for the invalid by means of putting boards and cushions between the seats. A lavatory carriage can almost always be obtained. The price for the reservation of a first-class compartment is usually that of four fares, or of a third-class compartment eight fares. By this means the patient can travel by the "crack" express trains to which most companies do not care to attach invalid coaches, as the train has to run fast and is timed so closely as not to allow for the pulling of extra weight. The Great Northern Railway charge six first-class fares if they have to run the carriage through to its destination.

The cheapest method of invalid travel, and also the least comfortable, is to get the company to bridge over the space between the seats of a first-class or third-class carriage. The expense will then be two fares for the invalid and one for the attendant. The rest of the carriage is open to the public.

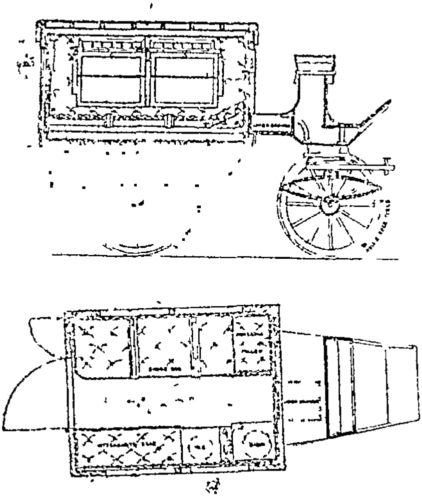
THE INVALID ROAD CARRIAGE.

Only three companies undertake the transference of the patient from house to house themselves. These are the Great Eastern Railway, the South-Eastern and Chatham Railway, and the London, Brighton, and South Coast Railway, all of which have special invalid road carriages built. In shape the vehicle is like an ordinary omnibus except that the driver's box is placed well in front and under it are the front pair of wheels. The body of the coach is carried on a single pair of large wheels and is swung by specially tested springs. On one side of the carriage is the invalid's couch, which is usually slung by springs; on the opposite side are a seat for the attendant, a water-closet, a basin, and a sink. The bridge that connects the driver's box and the body of the carriage is hollowed out to form a linen-drawer. There are two doors at the end of the carriage which enable the patient to be lifted straight out whilst lying on the couch and to be conveyed to the saloon or house (Fig. 6). Or if the journey is to be continued in the invalid road carriage it is placed upon a railway carriage truck where its wheels are fixed by means of blocks, &c., and to stop the oscillations leather bands are either fixed to some ironwork or passed over the roof of the carriage and the other ends fixed to the truck. In this way the carriage is tied tightly down with the springs tense. At the other end of the journey the carriage is detached and driven to its destination.

For the railway companies which do not undertake the transference of the patient from house to house Messrs. H. and T. Reading, of Ridinghouse-street, Langham-place, W., do the greater part of the traffic. They have two classes of vehicle for this method of travel. The first is the invalid's coach, which contains a spring-suspended couch and can seat two other people; and the second is the invalid's omnibus which is much more roomy, containing accommodation for four other people, water-closet, basin, &c., and is mostly used for surgical cases. These carriages are transferred and fitted on to a railway carriage truck, and dealt with by the various railway companies just as has been described above. They are heated by means of foot-warmers.

The prices for the road-carriage method of travel vary somewhat with the different lines. On the South-Eastern and Chatham Railway the charge for the road carriage, when occupied, is 1*s.* 6*d.* per mile, and when it is empty 6*d.* per mile, the minimum charge being 50*s.*, a first-class fare for each attendant, and a fee of 10*s.* 6*d.* for the company's caretaker. This includes a road journey of not more than three miles at either end. An extra charge is made if the carriage is not returned in 24 hours. On the Great Eastern Railway the charge for the road carriage when occupied is 1*s.* 6*d.* per mile and a first-class fare for each attendant. The company do not state any charge for the truck returning empty, any fee for the caretaker, or any minimum charge. The horses are to be provided by the hirer. On the London, Brighton, and South Coast Railway the charge for the road carriage, when occupied, is 1*s.* 3*d.* per mile, and when it is empty 6*d.* per mile, the minimum charge being 50*s*, first-class fares to be paid for all passengers. The contract includes three miles' drive at either end of the journey. They have the same rule as the South-Eastern and Chatham Railway as regards the retention of the carriage. The Great Northern Railway will undertake the transference of invalids from house to house by means of their omnibuses or by the St. John Ambulance Association. The Great Western Railway employ a private firm to move the patient from station to house and *vice versâ*. Messrs. H. and T. Reading charge one guinea for the first 10 miles and half a guinea for every further 10 miles, and 7*s.* 6*d.* as a fee for a special caretaker. Besides this there are the full charges of the railway company on which the patient travels.

FIG. 6



Invalid Road Carriage, Great Eastern Railway. This is fastened on to carriage-truck and so transported on the railway. In use on the Great Eastern Railway, South-Eastern and Chatham Railway, London, Brighton, and South Coast Railway, and on other lines by private firms

It will be seen that travel by rail in an invalid road carriage or omnibus presents but few advantages. It allows of the minimum of disturbance to the patient which is its great advantage. The objections to it are that the carriage as compared with a saloon is smaller, darker, and not so well ventilated, also the water-closet pan cannot be conveniently cleansed during the journey. Again it is the most expensive method of special railway travel just as it is the least convenient. The disturbance of the invalid can be minimised by driving the patient in one of the vehicles, carrying him on the couch to the saloon, when the couch is deposited upon the springs and is removed with the patient to the carriage at the other end of the journey. In this way the least disturbance to the invalid is obtained together with the greatest comfort and convenience. The invalid may easily be brought to the saloon by means of a hand carriage or moveable couch, such as is supplied by Messrs. Reading, and carried to the saloon; the same couch can also be used in the invalid carriage sent to meet him at the other end of the journey. The method of using the hand carriage lessens the expense and enables the invalid to travel in the saloon instead of on a truck.

INVALID TRAFFIC.

The amount of invalid traffic upon the different railways varies considerably. The lines that serve the southern counties are naturally those which have the most traffic and with this in view the first application for information was made to the London and South-Western Railway. This company on the average convey from 600 to 700 invalids yearly, as they have the monopoly of such places as Bournemouth, Swanage, Weymouth, Bude, Sidmouth, &c., which figure represents a far higher list than other companies, except the Great Western Railway, can show. Yet looking at the matter from the cold-blooded point of view of the shareholder invalid traffic does not pay, though half a loaf is better than no bread. Competition for invalid traffic hardly occurs at all, as each line taps a certain number of health resorts and so forth. Hence there has been no great stimulus for special improvements and cultivation of this branch of travel; so long as satisfaction is given all that is necessary is done. Beyond this it would seem unfair to expect more from a company which is a mercantile organisation and not a philanthropic institution. The London and North-Western Railway have no favourite health resorts upon their line and are chiefly employed with through traffic and long journeys. Hence their advocacy of the adoption of the luxurious family saloon for invalid travel. The introduction of the use of such a vehicle inaugurates quite a new era and corresponds in this branch to the introduction of corridor trains, &c., for ordinary travel. The price is the same as for a more primitive invalid saloon. There are certainly one or two alterations which would have to be made to make the family saloon an ideal invalid vehicle. This company also state that this traffic is worthy of special attention and is increasing. The Midland Railway carry over 400 patients in special saloons yearly, and, like the North-Western Railway, chiefly do through traffic. The Great Northern Railway Company of Ireland serve Rostrevor, the "Riviera" of Ireland, and supply an invalid chair for the conveyance of the patient from the station entrance to and from the carriage. The Great Southern and Western Railway of Ireland are of the opinion that this traffic is sufficient to warrant special cultivation; the saloons are used 40 times yearly. The North-Eastern Railway use their special saloons over 200 times a year and run them chiefly to Bridlington, Filey, Harrogate, Scarborough, and Whitby. The Great Eastern Railway have no favourite resorts upon their system and utilise their special carriages over 100 times yearly and their invalid road car only 40 times. The South Eastern and Chatham Railway report that this traffic is inconsiderable and although they offer special facilities it is insufficient to warrant special cultivation. On the Great Central Railway the traffic is small, but as they have recently constructed special saloons containing beds it cannot be unworthy of their attention. The Great Northern Railway's invalid traffic varies so much that it is difficult to express definite opinions as to its value. The London, Brighton, and South Coast Railway convey most of their invalid traffic to Brighton. Of the Scotch lines the Caledonian Railway serve principally Moffat and the Bridge of Allan; the Highland and Glasgow and South-Western railways do but little; the North British Railway send to North Berwick, Melrose, Peebles, St. Andrews, Comrie, Ballater, &c. The Great Western Railway have a very considerable invalid traffic from such health resorts as Torquay and Malvern, and as they, of all the companies, have catered most of all for the invalid, this company must be looked to for any future improvements.

In conclusion, thanks must be expressed to the general managers and superintendents of the line of the various railway companies for their kindness and help in drawing out this report.

REPORT OF THE MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD, 1899-1900.

III.[1]

In the previous notices reference has been made to the precautions which were taken against the spread of the plague and to the auxiliary scientific investigations which were undertaken by the medical officers of the Local Government Board. The ordinary routine work of the medical department of the Board remains for consideration. This work may conveniently be divided into three departments: (1) the precautions taken for the prevention of small-pox—that is to say, the work done in connexion with vaccination; (2) the local inquiries which are made in the case of insanitary areas and of towns visited by infectious diseases; and (3) the statistics compiled of the number of cases of infectious diseases and of the mortality which occurs from them. The figures and the statistical details in regard to the notified attacks and the registered deaths from certain infectious diseases in 93 urban sanitary districts in England and Wales are contained in Appendix A, No. 12. Information of a like character which is published for the several sanitary districts of the metropolis has been given in the columns of The Lancet week by week. Appendix A, No. 13, contains tables prepared (under the direction of the late Sir Richard Thorne) in regard to the incidence of infectious disease in urban districts and in the metropolitan areas for the five-yearly period 1893–97. The report by the vaccination officers (Appendix A, No. 1) refers to children whose births were registered during the year 1897. From the tables given it appears that in the case of 929,518 births 62·4 per cent. were successfully vaccinated; 11·2 per cent. died unvaccinated; 0 3 per cent. were said to be insusceptible to vaccination; and 3·4 per cent. were not vaccinated because certificates were obtained (under the Act of 1898) that the guardians of the children were afflicted by conscientious objections to the practice. Concerning the remaining 22 7 per cent. accurate information was wanting; included in this remainder are a number returned as "postponed," "removed," and "not to be traced." This percentage of defaulting or unreturned cases is larger than that in any record which has previously been made for England and Wales. In the case of London the number in default was no less than 29 1 per cent., and for the rest of the country it was 21·6 per cent. Reports on the inspection of public vaccination are given in Appendix A, No. 2, from which it appears that 1083 public vaccinators out of a total number of 1461 were recommended for award under the provisions of the Vaccination Act of 1867. During the year 1898 nearly 500,000 capillary tubes containing glycerinated calf lymph were sent to public vaccinators. Appendix A, No. 4, contains an account of the animal vaccine establishment at which during the year 1899–1900 2614 primary vaccinations were performed. The arrangements at the animal vaccine establishment which were made in the first place at the Jenner Institute for Preventive Medicine under the National Vaccine establishment proved inadequate, and at the close of the year 1899–1900 arrangements were being made for setting up several similar establishments on a wider and more satisfactory basis. Dr. Blaxall reports on the operation of the glycerinated lymph establishment which is under the management of the Local Government Board, and relates the difficulties which occurred in providing a sufficient amount of lymph. During the year 269 calves were sent from the department and all of these were examined by a veterinary surgeon after they were slaughtered and were found to be free from disease. Two others which seemed to be in health during the course of vaccination were found by the veterinary surgeon to be suffering from tuberculous disease. The lymph which had been obtained from these calves was at once destroyed; none of it was issued. It is not stated in the report that any examination was made of this lymph before its destruction.

Of all the work which is done by the medical officers of the Local Government Board certainly none is more important than the investigations which are made in regard to the incidence of disease in particular places and the tracing out of the conditions under which outbreaks of preventable disease occur. The amount of work of this kind which is done is enormous. The staff of the medical department have in the course of their duties to confer with the representatives of sanitary authorities in regard to the needs of their districts for the provision of by-laws of sanitary import; they have to consider proposals which are made for the provision of hospitals and in regard to the suitability of the sites proposed, and they advise also as to the best plan for the arrangement of the hospital buildings on the sites selected. During the year under review formal inquiries have been held by the medical inspectors as to the provision of hospital accommodation in over 60 towns and rural districts. Two local inquiries were held as to the provision of disinfectors and one as to the provision of a mortuary. In seven instances local investigations were made in regard to the adaptation to local needs of by-laws of sanitary import. Local inquiries were also held as to the best method for the disposal of sewage in various places, as to the provision of water-supplies, and in one case as to the formation of a joint board under the Rivers Pollution *Prevention Act* for the protection of the river Dee. The special requirements of particular parishes in regard to scavenging have been investigated and many inspections as to the cause of the incidence of disease have been made. In many of these cases facts of very great local interest have been obtained. Advice has been given to the local authorities as to the best method of getting over the difficulties into which they have fallen either from carelessness or from ignorance. Some of the facts which are put on record in the case of certain towns and rural districts are very striking and the clear way in which the reports are made renders it impossible for the local authorities to plead that the deficiencies to which their attention is called in the report have been mentioned with ambiguity.

A few samples will show the method which has been adopted and the way in which advice is given. Aldershot, with an estimated population of 16,500 and containing a camp with an estimated population of 13,894, suffered from severe epidemics of diphtheria. It was found that there was no isolation hospital and that no proper disinfecting apparatus had been established by the urban district council. The wells were liable to pollution, there were many old sewers, the sewerage was imperfect and the flushing insufficient. The arrangements made for carrying away the storm water were inadequate, the drainage of houses was often faulty, and the treatment of the sewage was not satisfactory. Houses were often damp, back yards were not paved, the by-laws referring to common lodging-houses were flagrantly neglected, animals were kept so as to become nuisances, and regulations as to cowsheds were not enforced.

Dr. H. T. Bulstrode's report on the sanitary condition of the borough of Windsor and upon the character of the town council's administration is of great interest. The past history of the management of this town has, as readers of The Lancet know, been most unsatisfactory. As long ago as the year 1885 the reports of our Special Commissioner on the poorer parts of the town appeared in our columns. A deputation of the town council afterwards waited on the Right Hon. C. T. Ritchie (in September, 1886) when an inspector was appointed to investigate the condition of the borough. As the result of this inquiry certain specific recommendations were made. Some years later (in 1890) Dr. H. Airy and Mr. Arnold Taylor were appointed by the Local Government Board to report on what had been done in the town and what still remained undone.[2] Public attention was again forcibly called to the state of the town in July, 1899, and Dr. Bulstrode was deputed to make an inquiry, the results of which have already been published in our columns.[3]

A report on enteric fever in the city of Chichester by Dr. T. Thomson and Colonel J. T. Marsh is of great interest and is worthy of careful study. We have not space to give even a summary of this report. It must suffice to say that it shows evidence of the greatest care in its production and that it is illustrated by a series of charts and maps. In the course of the inquiry the *investigators were led to consider* the possibility that the frequent recurrences of enteric fever at Chichester might be due to the pollution of the soil, and at their suggestion a bacteriological examination was undertaken. A few samples only were experimented upon by Dr Houston, to whom the research was intrusted, and the results were negative.

---

[1] Nos. I. and II. were published in The Lancet of June 15th (p 1705) and 22nd (p 1779), 1901, respectively.

[2] This report is dated Jan. 23rd, 1900.

[3] The Lancet, Dec. 1st, 1900, p. 1591, 1607.

One of the most thorough, exhaustive, and convincing reports in the Supplement is that by Dr G. S Buchanan upon epidemic enteric fever in the port of Falmouth. It is a model of what such a report should be and it is to be hoped that this research will be of use to the people of Falmouth, a town of great natural charm which has been rendered insanitary by the neglect and carelessness of its governing authority. It is to be feared that too often very little importance is attached to reports which are made at great trouble primarily for the sake of local authorities. The reports necessarily are not published directly they are made, the book in which they are contained is one which has not a very large circulation, and there are doubtless many people in Windsor, in Chichester, and in Falmouth who, although they are naturally interested in the healthiness of the places in which they live, may be still unaware that a very large amount of information which deeply concerns their welfare has been lately published.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, QUEEN SQUARE.

REPORT OF THE COMMITTEE OF INQUIRY.

THOSE of our readers who have followed the course of affairs at the National Hospital for the Paralysed and Epileptic, Queen-square, will be interested to know the salient features of the report and findings of the committee of inquiry which we are now enabled to lay before them. The whole report is too long to quote, so we are unable to do more than refer to the chief points We may first recall the fact that at a special general meeting of governors and members of the hospital on March 23rd, 1901, a resolution was passed "that a full and independent inquiry be at once instituted into the statement issued by the medical staff in May, 1900, the facility of inter communication between the medical staff and the board, including the demand of the former for direct representation on the Board; the position, function, and acts of the secretary-director, and the constitution, rules, and management of the hospital generally" The "committee of selection," chosen from governors of, and subscribers to, the hospital, elected as the committee of inquiry the following gentlemen, the chief points of whose report and findings we append Sir Edward Fry, Kt. (chairman), the Right Hon. the Lord Wolverton, Sir W W. Karslake, Kt, K C, Mr Timothy Holmes, F.R C S. Eng, and Mr Cecil Henry Russell

The allegations of the staff with regard to unsatisfactory food and insufficient supply of linen are found to be justified, while the nursing staff is declared to be inadequate The draw-sheets are washed in the hospital laundry, where only one woman is employed, and consequently the work is inefficiently done But the most important finding of these gentlemen, as in volving a most radical change in the method of management of the hospital, is to be found in paragraph 79, in which the opinion is expressed "that the office of general director in the hospital should be abolished and that the hospital should be carried on under one or other of the following schemes of government: (1) that the secretary should be entrusted with the ordinary duties of a secretary and that in addition he should be the chief executive officer of the Board of Management, but should be restrained from interfering in any way with the lady superintendent and the members of the medical and resident staffs and with all persons and things placed under their control, and that the house physician, lady superintendent, and secretary should be required in all cases of difficulty to consult, so far as possible, the chairman or vice chairman of the Board and to act in accordance with his advice; (2) that a resident medical superintendent should be appointed as a permanent official who should not only discharge the duties of the senior house physician, but should also be the responsible and resident head of the whole institution under the Board of Management" It will be seen that these recommendations if carried out will entirely remove the *fons et origo mali* to which the troubles that have arisen were all directly due—viz., the paramount and undesirable position of the secretary-director. Another important opinion expressed is that "the direct representation of the medical staff on the Board of Management would beyond all other methods secure the best and most satisfactory means of inter-communication between the medical staff and the Board, and that it would be to the great and permanent benefit of the hospital" The report goes with great detail into questions of finance, of the position of matrons, of the secretary-director, of payment by out-patients, and other matters, and throughout shows such care and good judgment that all concerned with the welfare of the institution must rest satisfied that a future based on the lines here laid down will be free from the frequent troubles of the past.

THE JUBILEE OF THE ISLINGTON MEDICAL SOCIETY.

WE regret that the pressure on our space caused by the meeting of the General Medical Council made it impossible for us to give a full report of the proceedings of the dinner to celebrate the Jubilee of the Islington Medical Society. The speech of the President gives the interesting history of the society and we have much pleasure in finding room for it. In proposing the toast of the evening, "Success to the Islington Medical Society,"

Dr. J G **GLOVER** said: The reasons which induce men to form themselves into societies or clubs are very various and sometimes curious. Addison with his usual humour has descanted on this point Probably there is no better reason for combining to form a society than community of profession. And of all professions in which the sociable principle is useful that of medicine stands foremost I have myself been consistent in this matter. For many years I have been a member of a local medical society, of the one whose jubilee we are celebrating to night, and of a central society—the Clinical Society of London—I have been a pretty regular attender and have always found myself amply repaid for the trouble and inconvenience of attending either. The anxieties of practice and the worry of exceptional cases are often much mitigated by an hour spent in the society of men of the same profession having similar anxieties and cases Unfavourable or suspicious thoughts of our neighbours are often corrected by such intercourse And when great epidemics rage and a point of contact is needed between the members of the medical profession and the medical representatives of the local sanitary authority, there is no point more obvious or more available than that supplied by the meeting of the local medical society It was doubtless with some such thoughts and views that a number of medical men met more than 50 years ago—for it was in 1850—in the house of Mr. Clifton, senior, 38, Cross street—a house which for a generation afterwards was well known to the profession, any member of which could be sure of receiving from its proprietor advice or help in any emergency or difficulty of practice On that memorable night in 1850 fourteen gentlemen were present Mr Clifton, senior, whose diploma dated back to 1807, presided. The others, as the founders, deserve to be remembered on this occasion. One of them—Mr J T. Jackson—happily still lives and is in practice, and might possibly have been with us to-night had he not been contending with his ninth attack of influenza The rest were Messrs Burrows, Camplin, Semple, Marston, Fullerton, Cattlin, Dreury, McOrea, Bradley, Bateman, Allan, and N. H Clifton These are much respected names in Islington—and within a very short time others were added, notably the late Mr Kesteven, Dr Stokes, and the late Dr Ballard, who afterwards did most admirable service in the medical department of the Local Government Board and enjoyed the high respect and affection of his chief, Sir John Simon These gentlemen were the founders of the society which still survives and their names are associated by us with all that is honourable and useful in practice Their example and their spirit still remain with us They little thought when they met in that room in Cross street in February, 1850, that 50 years afterwards so large and goodly a company would gather together to celebrate the occasion and to remember them with respect and gratitude They have disappeared; their work remains It is an old story.

"We men must vanish, be it so,
Enough if something from our hands have power
To live, and grow, and serve the future hour"

I should be wanting in my duty if I did not carefully enumerate the names of the five successive secretaries who have served the society and to whom it is under a great debt of gratitude—viz., Mr. N. H. Clifton, Mr. Keele, Dr. A. Reid, Dr. H. Frazer Stokes, and, now, Mr. David Keele. I need not say more to commend the toast of the evening, "Success to the Islington Medical Society." It has been a great bond of intercourse, a great source of help, and a means of friendship to its members; meeting at each other's houses; indulging in nothing stronger than tea and coffee; conducting its discussions mostly in a conversational way save on those many occasions when the society has been favoured with addresses on important subjects from consultants, metropolitan or provincial. No one in the profession is so secure in his position that he can be sure of not needing the help and sympathy of such a society. The good of medical men may be evil spoken of; their practice may be misunderstood and their fair name may have to be vindicated. The society has not been without its uses in that respect. I should be ungrateful if I did not give a somewhat personal illustration of its uses in other circumstances. Some years ago a somewhat ambitious though humble member of the profession was desirous of being elected to represent the general practitioners of England and Wales on the General Medical Council. If a man like my friend on the right, Sir William Turner, wanted such a post his name would be recognised throughout the country. But for a general practitioner in a suburb of London the problem was not so easy. I resolved to appeal in the first instance to my neighbours and to the members of this society. I felt that if I could not have their support I was not worthy of election by the profession. Dr. Stokes, whom we all miss much to night, became my chairman. Mr. Keele and the honorary secretaries spared neither time nor trouble in my behalf, all my neighbours gave me a good "send-off," and for 15 years I have been in the honoured position of Direct Representative, which I feel I owe not a little to the help of this society. I propose to you its prosperity, and can wish no better for the society and the district than that the traditions and the spirit of the Cliftons and Cattlins of Islington may long survive.

THE INCORPORATED MEDICAL PRACTITIONERS' ASSOCIATION.

The tenth annual meeting of the above association was held at the Holborn Restaurant, London, W.C., on June 20th to receive the report of the central council and to elect officers for the ensuing 12 months. The report, which was unanimously adopted, stated that during the last 12 months the association had steadily grown in usefulness and influence, whilst the financial position was now more satisfactory than it had been for some years past. As in former years the association through its council and individual members, had strenuously and successfully opposed the Bill for the registration of midwives. Reference was made to the club and medical aid question and members were recommended to combine with their medical colleagues in establishing local centres of provident medical aid to be absolutely independent of lay control. The report was unanimously adopted. The election of officers was then proceeded with and Dr. Henry Blake (Great Yarmouth), on the nomination of the Great Yarmouth branch of the association, was unanimously elected president for the ensuing 12 months. Mr. J. S. E. Cotman, the retiring President, was elected a life vice-president. Dr. C. T. Aveling having served as a member of the central council for three years was added to the line of vice-presidents. The following names were added to the list of members forming the General Council:—Mr. A. Phillips Hills, Dr. A. L. Mathieson (Sheffield), Mr. A. H. Moxon (Great Yarmouth), Mr. J. C. Smith, and Mr. R. F. Tomlin (Wood Green). Mr. F. Greave was re-elected honorary treasurer, Mr. George Brown honorary secretary, and Mr. J. S. Cotman general secretary At the conclusion of the meeting dinner was served in the Gordon Salon, the newly-elected President, Dr. Blake, being in the chair. About 40 members and guests were present, among whom were Dr. H. Macnaughton Jones, Dr. F. J. Allan, Dr. J. Pollock Simpson, Dr. Frederick Spicer, Mr. George Jackson, (Plymouth), Mr. G. H. Broadbent (Manchester), and Dr. Rivers Willson (Oxford). Replying to the toast of the evening, "The Incorporated Medical Practitioners' Association," which was proposed by Mr. J. S. E. Cotman, the President said he was gratified to learn from his predecessor that the association was in a thoroughly satisfactory state. Like the late president, he felt that as long as they kept to their published programme the association must progress. Referring to the club question with which they had had to deal at Great Yarmouth Dr. Blake said that the local practitioners had lost practically all their clubs through insisting on the adoption of a wage-limit and class-limit for members. Their ruin was foretold, but none of them had been ruined, indeed they rejoiced in their freedom from clubs. Ruin was, however, threatening the other side. They—the late club medical officers—were more than ever convinced that a wage-limit and class-limit should be insisted upon, and they now realised that even properly regulated clubs are not necessary for the support of a general practice. Further, he would say that a practice which was improved by a women and children's club must be a poor practice indeed. Referring to the difference between the Conjoint Board for England and the General Medical Council Dr. Blake said his sympathies were with the Conjoint Board. He regarded the action of the Council in forcing boys to go to London to study science when they might spend the year to better advantage at some of the excellent schools recognised by the Conjoint Board as prejudicial to the interests of the profession. In conclusion, he would give the assurance that the officers of the association would during the ensuing year do all they possibly could to promote the interests of the profession. The toast of "The Visitors," proposed by Mr. Joseph Smith, was responded to by Dr. Macnaughton Jones, and Mr. Jackson responded to the toast of the "Provincial Members," which was proposed by Mr. Brown.

PLAGUE IN EGYPT.

According to the system which has obtained in Egypt ever since an English element was introduced into the sanitary department, the greatest possible publicity is given to all outbreaks of infectious disease. Formerly concealment used to be the main object, but now the public receive warning in due time and are consequently able to adopt precautionary measures with a fair prospect of success. As regards plague it is the present custom of the head of the sanitary department to submit weekly reports during the continuance of each epidemic of the disease to the Minister of the Interior, for such action as that official and his adviser may deem desirable. The first of these reports for the current year has been forwarded to us. It is dated "Cairo, June 9th," and covers four type-written pages of foolscap. In the following summary the chief points will be found briefly stated.

On June 1st two suspicious cases were reported at headquarters from Zagazig, which is one of the most important towns in the Delta and has a population of 35,715, including 1572 foreigners. The next day Major C. Garner, R.A.M.C., and Dr. Bitter, the chief bacteriologist of the department, proceeded to the spot, the former to take "immediate measures to isolate the sick, keep all contacts under control, and thoroughly disinfect the houses and their neighbourhood where the cases had been discovered"; and the latter to make a bacteriological examination of the affected cases. On the following morning Dr. Bitter pronounced the disease to be plague and to the same cause he also ascribed a death which had occurred out of the hospital. On June 4th and following days several more patients were isolated in the infectious hospitals which Major Garner had extemporised for Europeans and natives respectively, but happily most of the cases were of a mild character. The total number of persons affected is not stated, but with regard to the etiology of the outbreak Mr. H. H. Pinching, the present head of the sanitary department, who himself visited Zagazig on June 6th, has no doubt that the disease must have existed some time in the town and remained unrecognised owing to its subtle nature and to the extreme difficulty which observers who have had no previous experience of plague must find in diagnosing it. "I cannot help thinking this is almost unavoidable," continues Mr. Pinching, and he also has grave doubts whether the channel of communication through which the infection was carried to the town of Zagazig will ever be discovered. The place is in constant communication with Port Said, where there was plague last year, and the Greeks and Jews among whom the disease occurred, frequently travel to and from Alexandria with all kinds of merchandise.

On June 2nd a suspicious case was signalled from Minieh, which is a considerable town situated in Middle Egypt and having a population of 20,404, of whom not more than 280 are foreigners. Dr. Bitter and Dr. H. O. Goodman proceeded there on June 3rd and found a young man, a native, about 25 years of age, suffering from suspicious symptoms. The case having been bacteriologically diagnosed as plague, measures similar to those at Zagazig were promptly taken, and up to the date of the report no further cases had been discovered. There was, it is true, an old woman, a Copt, whom the local inspector thought presented symptoms resembling those of plague, but when at last she was found and examined the bacteriological results were negative. As soon as the relatives of this patient heard of the coming of the officials from Cairo they were stricken with unreasoning terror and concealed the poor creature in some remote oubliette, whence it was only after a lengthened search that Dr. Goodman was able to rescue her. All efforts to trace the source of the infection remained fruitless. Some 16 days before the young man had been at a fair in the vicinity, and according to the local sanitary inspector it was on his return that he first fell ill.

On June 6th a native, about 25 years of age, was observed to be suffering from marked symptoms of plague at Mansourah, which is a large town in the delta standing on the Phatnitic branch of the Nile with about 35,000 inhabitants, including 1639 foreigners. Graham Bey, who examined the case bacteriologically, pronounced it to be one of plague, and the man subsequently died. It was ascertained that he had arrived at Mansourah on June 5th, having left Zagazig three days previously. All the customary sanitary measures were put in force, and up to June 9th no further outbreak had been reported.

The following case, the last on the list, is incomplete, for it is not stated what punishment, if any, was meted out to the inhuman clerk. On June 7th the corpse of a Soudanese boy who had died from plague was found in the closed house of a clerk employed in the Parquet at Zagazig. When this person and his family found their servant "*in extremis* they left him in the house to die by himself, locked the door, and all fled" to Kafr-el-Zayat, which is another Deltaic town situated on the Canopic branch of the Nile. This Government clerk, who must have been a man of some education, knew perfectly well that his servant was suffering from a disease which the sanitary officials were doing their utmost to subdue, and yet he "in no way notified the case but left the wretched boy to die in a most heartless manner, and did his best to infect a town which up to the present has remained immune."

In conclusion Mr. Pinching says: "I think it my duty to point out to your Excellency that I consider the position of the country with regard to the probability of the disease assuming an epidemic form is more serious than it has been for the last two years." The head of the Egyptian sanitary department bases this important warning on the fact that several towns far apart from each other are known to have been contaminated, as well as on the probability that other intermediate towns and villages must have likewise become infected without information to that effect reaching him. "Happily, the general health of the country is at present good, and the mortality in general, and in the towns infected, low."

THE NEW WING AT ST. THOMAS'S HOSPITAL.

ON June 20th Lord Lister opened a new wing at St. Thomas's Hospital. The building consists of two operating theatres with anæsthetic rooms, a children's ward, and various rooms for staff, assistants, store room, &c. The cost of these additions to the accommodation of the hospital is about £20,000.

The special points to be noticed with regard to the theatres are the marble auditoriums of three rows only; the rounding off of all angles to prevent the collection of dust; the sterilisation of instruments under the surgeon's eye in the theatres; provision for purifying soiled clothes, and mackintoshes by steam; and, the sterilisation of instruments, dressings, ligatures, &c., solely by means of heat. Lighting is effected by means of a window in the roof and by electricity. All persons engaged in the operation on the floor of the theatre will wear sterilised overalls and clean rubber boots which are only to be used in the theatre. The lower 6-7 feet of the walls are of marmorite slabs and the upper parts are of white enamel. The passage outside the theatre is forbidden to all except operators and assistants.

The children's ward is prettily decorated with Doulton ware panels in shades of pink, blue, and green, illustrating fairy tales and nursery rhymes. These tiles are the gift of Mr. S. G. Holland, one of the governors of the hospital, in memory of his daughter Lilian. Outside the children's ward, which contains 15 cots, there is a balcony about nine feet wide covered by a sloping roof. The view of the river Thames and the Houses of Parliament is, however, unfortunately obstructed from this balcony by the inelegant roof of the nurses' dining room, and it is to be hoped that it is not yet too late to remedy a decided fault.

The other rooms include a staff room (apart from the theatre) where tea will be served to the visiting staff, an anæsthetic recovery room next to the lift, and store-rooms. The ventilation of the block is accomplished by means of the Plenum system. The air is cleaned by three screens of cocoanut matting over which water is trickling continuously. Between each screen and outside them are coils of pipes for heating or cooling the air which is driven by a fan worked by a two-horse dynamo.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6333 births and 3301 deaths were registered during the week ending June 22nd. The annual rate of mortality in these towns, which had been 16·3, 15·2, and 14·5 per 1000 in the three preceding weeks, rose again to 15·0 per 1000 last week. In London the death-rate was 13·8 per 1000, while it averaged 15·8 in the 32 large provincial towns. The lowest death-rates in these towns were 8·0 in Brighton, 10 7 in Norwich and in Portsmouth, 10·8 in Croydon, and 11·5 in Huddersfield; the highest rates were 18·3 in Manchester, 18·4 in Sunderland, 18 8 in Halifax, and 21·1 in Liverpool. The 3301 deaths in these towns last week included 356 which were referred to the principal zymotic diseases, against 320 and 357 in the three preceding weeks; of these 101 resulted from measles, 77 from diarrhœal diseases, 68 from whooping-cough, 59 from diphtheria, 37 from scarlet fever, 13 from "fever" (principally enteric), and one from small-pox. No death from any of these diseases was registered last week in Derby or in Burnley; in the other towns they caused the lowest death-rates in Croydon, Norwich, Blackburn, and Huddersfield, and the highest rates in West Ham, Bolton, Salford, Halifax, and Hull. The greatest proportional mortality from measles occurred in West Ham, Bolton, and Hull; from whooping-cough in Plymouth, Sunderland, and Newcastle; and from diarrhœal diseases in Wolverhampton, Liverpool, and Bolton. The mortality both from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 59 deaths from diphtheria included 18 in London, five in Sheffield, four in Salford, and four in Halifax. One fatal case of small-pox was registered in Liverpool, but not one in any other of the 33 large towns; and only one small-pox patient was under treatment on Saturday last, June 22nd. in the Metropolitan Asylums hospitals. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2707, against numbers increasing from 1522 to 2594 on the eight preceding Saturdays; 368 new cases were admitted during the week, against 317, 314, and 323 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 240, 187, and 159 in the three preceding weeks, further declined last week to 150, and were 53 below the corrected weekly average. The causes of 33, or 1·0 per cent., of the deaths in the 33 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Manchester, Bradford, Newcastle, and in 14 other smaller towns; the largest proportions of uncertified deaths were registered in Portsmouth, Norwich, Liverpool, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 20 7 to 16·9 per 1000 in the four preceding weeks, rose again to 18 6 per 1000 during the week ending June 22nd, and showed an excess of 3·6 per 1000 over the mean death-rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 14 1 in Leith and 14·5 in Greenock to 18·5 in Edinburgh and 19·9 in Glasgow. The 592 deaths in these towns included 44 which were referred to whooping-cough, 25 to measles, 13 to diarrhœa, eight to scarlet fever, three to diphtheria, three to "fever," and one to small-pox. In all, 97 deaths resulted from these principal zymotic diseases last week, against 102 and 75 in the two preceding weeks. These 97 deaths were equal to an annual rate of 3 0 per 1000, which was 1·4 above the zymotic death-rate during the same period in the 33 large English towns. The fatal cases of whooping-cough, which had been 48 and 32 in the two preceding weeks, rose again last week to 44, of which 24 occurred in Glasgow, 12 in Edinburgh, four in Leith, two in Dundee, and two in Greenock. The deaths from measles, which had been 21 and 17 in the two preceding weeks, rose again to 25 last week, and included 15 in Glasgow, three in Edinburgh, three in Dundee, and three in Leith. The fatal cases of diarrhœa, which had declined from 30 to 17 in the four preceding weeks, further decreased last week to 13, of which eight were registered in Glasgow and three in Paisley. The deaths from scarlet fever, which had been one and three in the two preceding weeks, further rose to eight last week, and included five in Glasgow. The three fatal cases of diphtheria corresponded with the number in the preceding week, and included two in Edinburgh. The deaths referred to different forms of "fever," which had been six and three in the two preceding weeks, were again three last week, of which two were recorded in Glasgow, where the fatal case of small-pox also occurred. The deaths referred to diseases of the respiratory organs in these towns, which had been 98 and 101 in the two preceding weeks, declined again last week to 92, but showed a slight excess over the number in the corresponding period of last year. The causes of 32, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 20 0 and 19 6 per 1000 in the two preceding weeks, rose again to 20 2 during the week ending June 22nd. During the past four weeks the death-rate has averaged 20 3 per 1000, the rate during the same period being 14·3 in London and 19 5 in Edinburgh. The 183 deaths of persons belonging to Dublin registered during the week under notice were four in excess of the number in the preceding week, and included 10 which were referred to the principal zymotic diseases, against five, nine, and eight in the three preceding weeks; of these, three were referred to whooping-cough, three to diarrhœa, two to "fever," one to scarlet fever, and one to diphtheria. These 10 deaths were equal to an annual rate of 1·4 per 1000, the zymotic death-rate in London also being 1·4 per 1000, while in Edinburgh it was 2 9 per 1000. The fatal cases of whooping-cough, which had been five and three in the two preceding weeks, were again three last week. The deaths from diarrhœa, which had been two and four in the two preceding weeks, declined again last week to three. The 183 deaths in Dublin last week included 17 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths of infants showed a marked decrease from the number in the preceding week, while the deaths of elderly persons had only slightly declined. Nine inquest cases and seven deaths from violence were registered, and 57, or more than three-eighths, of the deaths occurred in public institutions. The causes of eight, or more than 5 per cent., of the deaths in Dublin last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Deputy Inspector-General of Hospitals and Fleets Robert Grant has been promoted to the rank of Inspector-General of Hospitals and Fleets in His Majesty's Fleet.

The following appointments are notified: Staff Surgeons: E. Corcoran to the *Magdala* and W. G. K. Barnes to the *Resolution*. Surgeons: J. F. M. McDougall to the *Harrier* and R. M. Richards to the *Wildfire*.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel William Wippell Pope retires on retired pay. Civil Surgeon Richard Chapman Wilson to be Lieutenant. Lieutenant P. H. Henderson is attached to the Station Hospital, Poona, for duty. Lieutenant-Colonel A. Young is selected for duty at Perth. Captain C. B. Lawson is posted to the Station Hospital, Western Heights, Dover, for duty. Major C. R. Elliott is appointed Sanitary Officer, Bombay Command. Lieutenant C. R. L. Ronayne, attached to the Station Hospital, Poona, proceeds to Ahmednagar for duty at the Station Hospital there. Captain C. T. Samman proceeds to Woolwich for duty. Lieutenant-Colonel J. Daniel Crowe, A.M.S. (retired), has been appointed to the medical charge of troops at Weymouth.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Lieutenant H. L. de Legh to be Surgeon-Captain; Surgeon-Captain T. F. Dewar to be Surgeon-Major.

VOLUNTEER MEDICAL STAFF CORPS.

The Glasgow Companies: Surgeon-Lieutenant-Colonel Bruce Goff, retired, late 2nd Volunteer Battalion the Cameronians (Scottish Rifles) to be Honorary Commander.

IMPERIAL YEOMANRY.

Unattached: Temporary Captain F. A. Hadley resigns his commission.

VOLUNTEER CORPS.

Rifle: 2nd Volunteer Battalion the Queen's (Royal West Surrey Regiment: Captain and Honorary Major Francis Rutherford Russell, retired, to be Surgeon-Major. 2nd Volunteer Battalion the King's Own (Royal Lancaster Regiment): Bertram Whewell Hogarth to be Surgeon-Lieutenant. 1st Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant K. W. Monsarrat to be Surgeon-Captain. 1st Volunteer Battalion the Duke of Cornwall's Light Infantry: Francis Chown to be Surgeon-Lieutenant. 1st Cinque Ports: Surgeon-Lieutenant H. J. Holman to be Surgeon-Captain. 4th (Nottinghamshire) Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Lieutenant W. T. Crawford to be Surgeon-Captain. 2nd Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant F. H. Westmacott to be Surgeon-Captain. 2nd Volunteer Battalion the Durham Light Infantry: Thomas Hillhouse Livingstone to be Surgeon-Lieutenant. 2nd (Renfrewshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain A. Donald resigns his commissisn; Surgeon-Lieutenant H. C. Donald to be Surgeon-Captain.

SOUTH AFRICAN WAR NOTES.

Civil Surgeon Wilbond is reported to be improving (June 24th).

Civil Surgeon H. O. Baker has been discharged from hospital to duty.

Civil Surgeons Pridmore, Martine, Weir, and Walker are on passage home.

Colonel Kilkelly, C.M.G., Grenadier Guards, reports that on May 29th, there remained in the Imperial Yeomanry Hospital, Pretoria, 38 officers and 338 non-commissioned officers and men. The total admissions to the hospital since the date of opening number 4258; of these 922 were out-patients. Enteric fever and dysentery still prevail.

AFFAIRS IN SOUTH AFRICA.

There is nothing of a very important or striking character to be chronicled from the seat of war. Despite of the raiding that continues on the part of the Boers the process of attrition is *steadily but surely continuing also.* Lord Kitchener, telegraphing from Pretoria, stated that since his last despatch the columns had reported 41 Boers killed, 27 wounded, 160 prisoners, 70 surrenders, 41,800 rounds of small arms ammunition and 264 wagons captured, besides horses and stock. The slowness of the operations recently reported from South Africa has given rise to the impression that the reinforcements, especially of a mounted kind, are inadequate. Be this as it may, it is impossible to doubt that the vast extent of country that has to be guarded and over which the operations extend, the splitting up and dispersal of the Boers into numerous small bodies, and the enormous number of prisoners, women and children committed to our charge and requiring to be treated in accordance with modern ideas of humanity and philanthropy, make up a formidable as well as a very costly undertaking—amounting to a weekly expenditure of some million and a quarter. While many people at home are declaiming against the evils of camps of concentration and our inhumanity, independent military critics who have been present at the seat of war are, on the other hand, astonished at the humane consideration, amounting as they think to weakness, with which this war has been waged. Madame Alice Bron, in her "Diary of a Nurse in South Africa," has a very different story to tell and gives a very different picture of the Boers to that presented by their friends and encomiasts in this country and abroad. There is no denying the fact that the army medical officers who have served in South Africa are, as we have said, dissatisfied and disappointed with the adverse criticism to which they have been exposed on the part of a number of irresponsible people who were simply incompetent to form anything like a correct estimate of the situation or of the excellent professional and administrative work which was done during this campaign—and generally under the most difficult and trying circumstances. Nor, it must be admitted, are speeches like that delivered by Dr. R. Craig Dun on the occasion of a dinner recently given by the profession in Liverpool to the civil surgeons lately returned from active service in South Africa calculated to allay this feeling. We take our account from a report which appeared in the *Times* of June 21st. Dr. Dun's experiences in the field appear to have been the very opposite of those obtained by some of the most eminent hospital surgeons of this country and contrary to the conclusions arrived at by the South African Hospitals Commission But Dr. Dun, a civilian volunteer surgeon, has no hesitation and apparently entertains no misgiving in regard to his views. He has the courage of his opinions and is equally ready to disparage the army hospitals and to condemn the field medical system which has been tried, adopted, and pursued by every other European military power as well as by ourselves. The army is seemingly in future wars to be for the hospitals and not the hospitals for the army. The British soldier is notoriously a very courageous man and not easily daunted, but he must have food and ammunition to be of any service, and he does not find these on the veldt like manna from heaven. Any alleged breakdown of the hospital system that might have occurred at Bloemfontein was due to the fact that Lord Roberts had to provide his troops with these essentials and to take up at all hazards all the transport for this purpose. Who doubts for a moment that, being in supreme command of the army in the field, he was perfectly justified in what he did and that he would not hesitate to do the same again to-morrow under similar circumstances, and had he boldly said so and declared that the responsibility was solely and entirely his who can doubt that he would have had the nation at his back? Be that as it may, here is what Dr. Dun is reported in the *Times* to have said:—

> Dr. R. Craig Dun described the relation of the civil medical officer to the Army Medical Corps Referring to the absence of equipment for troops going out, he said that the medical department of the War Office had no idea of the magnitude of the work before it. He denounced the field hospital system, by which the sick and wounded had to be carried about for three weeks and live on rations served out to the Army Service Corps. He compared the military hospitals with the civil hospitals in South Africa much to the disparagement of the former. Speaking of the Ho[illegible] to civil surgeons as a roaring [illegible] and quite rightly so, because [illegible] general public at home to beli[illegible] had said was true. It was mu[illegible] though as a matter of fact it w[illegible] issued a private report to members of the House of Commons, and someone had told him that the Commission fully realised what the state of affairs in South Africa was, and that it was the intention of the country to see that such a state of affairs did not occur again

Our Liverpool correspondent gives his account of the speech in another column, but does not represent Dr. Dun as alluding to any "private report" of the Hospitals Commission. We are in a position to state emphatically that no such report was made.

NAVAL AND MILITARY CONCERT.

A grand naval and military concert under the patronage of the King and the Queen will be held at the Crystal Palace in aid of service charities on Saturday afternoon, July 6th, at 3 P.M., for the benefit of the following funds:—The Soldiers' and Sailors' Families Association, the Royal Naval Fund, the Soldiers' Daugters Home, the Royal School for Daughters of Officers of the Army, the Royal School for Naval and Marine Officers' Daughters, the Soldiers' and Sailors' Help Society, Lady Lansdowne's Officers' Families Fund, the National Memorial Gordon Boys' Home, Lady Dudley's Fund for Invalid Officers and Nurses, and the Central British Red Cross Committee. Tickets for reserved and numbered seats are one guinea and half-a-guinea respectively and include admission to the Palace. They may be obtained from the honorary secretary and treasurer, Mrs. Ronalds, 7, Cadogan-place, or from any of the usual libraries and ticket agencies. Extra fast trains will be run on the day in question and a special display of fireworks will be given in the evening. As a musical event the concert, with the massed bands of 20 regiments numbering over 600 picked musicians, will be a novelty. Full particulars of the programme will be announced in a few days Miss Margaret Macintyre, Miss Marie Brema, Mr. Ben Davies, Mr. Santley, and Signor Ancona have kindly promised their assistance.

DEATHS IN THE SERVICES.

Lieutenant-Colonel George Lemon Walker, I.M.S., Professor of Medical Jurisprudence in the Medical College, Madras, recently, aged 52 years. He entered the Indian Medical Service in 1876, was promoted to surgeon-major in 1888, and to surgeon-lieutenant-colonel in 1896 He took part in the operations against the Rumpa rebels in 1879.

Correspondence.

"Audi alteram partem."

IODIDE OF POTASSIUM IN ASTHMATIC AFFECTIONS.

To the Editors of THE LANCET.

SIRS,—Since you did me the favour of publishing my brief communication on Iodide of Potassium in Asthmatic Affections[1] I have been corrected in one detail, of which it is proper that your readers should be informed. The remarkable experience—or rather experiment—of Principal Barclay in analysing a very complex prescription so as to bring out, in his own person, the special virtues of the iodide was (as I stated) a "cardinal fact" in my own experience and one carrying a lesson of considerable importance. I have since been informed that my "cardinal fact" is distinctly, though anonymously, set forth in the late Dr. P. M. Latham's works[2] and I am glad to acknowledge this, because in Dr. Latham's admirable language the moral and therapeutic lesson of the case stands out perhaps even better than in my short paragraph; only it does not appear that Dr. Latham was cognisant at first hand of the details, otherwise he would have known that there was nothing haphazard about the experiment (as is suggested), but that it was deliberately and persistently carried out upon my suggestion, conveyed through the Principal's regular medical advisers I mention this once more, not to claim any credit for it, but because I am still under the impression that Principal Barclay's case was probably the first in which a really well-grounded conviction was arrived at as to this particular action of the iodides, and it has become a historic *datum* of more or less importance.

I am, Sirs, yours faithfully,
W. T. GAIRDNER.

Edinburgh, June 25th, 1901.

UNBOILED *v.* BOILED MILK.

To the Editors of THE LANCET.

SIRS,—The practice of milk-boiling has been so strenuously urged, almost unanimously, by the profession, and has consequently become so general, that it is with some diffidence that I venture to raise the question of its wisdom. That raw milk may be contaminated by various bacilli—such as the bacillus tuberculosis, the bacillus typhosus, the bacillus diphtheriæ, the streptococcus scarlatinæ, and even, through the addition of polluted water, the bacillus enteritidis sporogenes and the bacillus coli communis—I fully admit. But are these evils so frequent and so fatal as to counterbalance the disadvantages arising from the diminution or destruction of the nutritive properties of milk which boiling undoubtedly produces? And the gravity of the case is increased when it is remembered that milk should be the staple food of the infant, the child, the aged, and the sick.

---

[1] THE LANCET, June 3rd, 1901, p. 1520
[2] New Sydenham Society's edition, vol. ii., p 513.

The occurrence of illness, epidemics, and death from the presence of extraneous poisons in "fresh" or raw milk is certain, but could not these be met by greater care, enforced by more severe penalties for neglect, and by stopping the supply of milk when disease occurs without habitually destroying the nutritive value of milk by artificial means? When railway accidents happen which maim and kill the advice tendered is not that travellers should stay at home, but that more stringent precautions should be taken to prevent such disasters. *And in the case of milk epidemics the remedy* should not be habitually to diminish or to destroy the nutritive value of the most valuable food we possess, looking to the number whom it concerns, but to require sufficient precautions regulated by efficient inspection at the source of supply. I maintain that even the accidental poisoning of milk is much less baneful to the community generally than the destruction of its nutritive qualities, which means for artificially-reared infants rickets, infantile scurvy, and tuberculous diseases and for the aged and the sick deficient nutrition. These sufferings are incalculable and often life-long, while those of epidemics are usually limited, owing to the care expended on their investigation by the medical officers of health.

That "fresh" or raw milk cannot be so deleterious an article of food as is asserted is proved beyond all question by the fact that during a period of 30 years in which I have had charge of the health of a very susceptible community—a great public school—I have had only four cases of typhoid fever, three cases of diphtheria (not one of which was occasioned by milk), and none of tuberculous disease, and yet the boys drink an enormous quantity of milk—so great that I have been censured by a member of the profession for the quantity I advocate and have secured for their welfare, which is never boiled and rarely warmed. In my daily practice outside the school I am perpetually asked by those who have children to rear whether the milk ought to be boiled and my invariable answer is in the negative. For, if there is one thing that is essential to the vigorous growth of children it is a plentiful allowance of milk. How children can be expected to develop on boiled milk and the constant restriction of sugar is beyond comprehension. It is clear to me that the educated, as well as the uneducated, public require to be taught—

1. That the nutritive value of milk is very largely diminished by boiling.

2. That this is true also of sterilised milk, which should therefore only be used for a short time in order to tide over a difficulty in the early artificial feeding of infants. The nature of the change produced by the heating of milk, and which is so deleterious, is not accurately ascertained, but I will produce an instance of its effect. Some time since I attended an infant who did not thrive and who was perpetually crying on the slightest movement. For this I was unable to account although I was answerable for its feeding. Because of its condition another opinion was sought and the child was declared to be syphilitic, so that mercury with chalk was prescribed, although, beyond doubt, no such taint existed in either parent. By-and-by, however, unmistakeable signs of infantile scurvy appeared, with the extreme pallor, the pain on movement of its lower limbs, the typical epiphyseal swellings of the lower ends of the tibiæ, and all the other symptoms so accurately described by Sir Thomas Barlow. It turned out that while I was responsible for the food a lady gossip was answerable for the milk-boiling, hence the result. As soon as this was rectified and anti-scorbutic food was administered the child began to thrive and rewarded the mother for the care bestowed.

3. That while milk contains all the essential ingredients for growth, as well as nourishment—viz., albumin, fat, sugar, salts, and water—it contains no starch. This addition to the infant's food which is so prevalent is most injurious to the welfare of the child. Until I can be convinced that the value of milk-boiling outweighs its defects I have but the advice to give to those who do me the honour to consult me—Don't! If ever the time should arrive that milk must be invariably boiled it should be done as soon as it leaves the cow's udder and before it is distributed. But, at present, the issues of boiled milk, as I have pointed out, are certain, those of unboiled milk are remote. The remedy for the disadvantages of "fresh" or raw milk is not wasteful destruction of its nutritive value by boiling, but the enforcement of efficient inspection of dairy cows, dairies, milkers, and dairy keepers who supply it wholesale and the ensuring of cleanliness also on the part of the retailer.

I am, Sirs, yours faithfully,
CLEMENT DUKES, M.D., F.R.C.P. Lond.

Rugby, June 14th, 1901.

"THE CONTAMINATION OF POST-OFFICES."

To the Editors of THE LANCET.

SIRS,—*Apropos* of your article in THE LANCET of June 22nd, p. 1794, on the "Contamination of Post-offices," I should be obliged if you could allow me a little space in which to point a moral from the action of the French Government. And *en passant* may I remind you that I sent you a marked copy of the *Telegraph Chronicle* some time back, in which I published a complete translation of Dr. Mignot's report and the decrees thereanent which M. Millerand had promulgated. In 1895 I tendered evidence to Lord Tweedmouth's Committee which was designed to prove an unduly high incidence of phthisis among certain classes of employés in the English Post-office. This evidence received considerable attention from THE LANCET and other medical journals. In reply to my contentions it was stated that my figures were unreliable and referred to damaged lives. This contention I combated, and after some years of further study of the matter I am still of opinion that the statistics I gathered gave a substantially accurate view of the mortality rate from phthisis in the British postal service. They showed that of every 100 deaths among sorting clerks and telegraphists during a period of 10 years 45 4 per cent. were due to phthisis. Following upon the notice attracted to the question in 1895 the Postmaster-General commenced the publication of some meagre statistics in his annual report, and has continued to give these statistics up to the present time. They are unclassified, and the whole of the varied occupations of the postal service are lumped together as though they were a single class performing identical work under identical conditions. But even these unsatisfactory figures give the following result: the total annual loss from phthisis during the year 1896 was 2·4 per 1000 living, in 1897 it was 1 9; in 1898 it was 1 9; and in 1899 it was 1·7. The figures refer to the established staff, every member of which is a carefully selected life and has passed a series of severe medical examinations before entry into the service. According to the Registrar-General's returns for the same years the loss among the general population from phthisis was 1 3 per 1000 living. It is unnecessary to remind readers of THE LANCET of the serious nature of this comparison. The loss among specially selected lives is considerably higher than among the general population, which includes the weak, the sick, and the rejected of the Post Office. In view of the gravity of these facts I have received permission to introduce the subject in the Section of State Medicine of the British Congress of Tuberculosis, and I trust that this will tend to bring into operation some such steps as have been adopted by the French Post-office. The English postal servants are not quite so helpless as your correspondent represents the French employés to be, and this may be the reason why the charity of the Postmaster-General has not yet reached them.

There is a curious coincidence in the fact that in the same issue of THE LANCET in which you record the generous action of the French Minister towards his minor employés you also publish a reply by Mr. Austen Chamberlain to Sir Walter Foster, M.P., in which he declines a return which would show the real loss from phthisis among the English postal staff. I have been using the best endeavours of a layman to draw attention to this matter for some six years; may I now hope that you will give me the useful support of the prestige and publicity of THE LANCET? Every life lost from a preventable disease is a wasted life. "If preventable, why not prevented?" said King Edward on a memorable occasion. One of the best fields in which to commence operations is among the 160,000 employés of the British Post-office. The measures adopted in France afford a useful example of what can be done.

I am, Sirs, yours faithfully,

Barnes, S.W., June 21st, 1901. CHARLES H. GARLAND.

OPTIC ATROPHY AND TABES DORSALIS.

To the Editors of THE LANCET.

SIRS,—There has to the best of my knowledge never been any theory which satisfactorily accounts for the fact that double optic atrophy coming on early in locomotor ataxia so frequently causes arrest of the disease, and in some cases even permanent improvement. I, therefore, venture to propound the following which I think will account for it in great part, if indeed it does not do so entirely.

The tabetic patient in consequence of failure of eyesight is forced to rely for all his movements more and more on his muscular sense, ordinary sensation, sense of localisation and coördination. He is, in fact, actively engaged in trying to restore the impairments and re-educate these senses every minute of the day when not asleep. The effects of coördinate [illegible] well known in [illegible] is compulsory [illegible] e same result, though in a more powerful manner, as it is continually being called into demand? And here, of course, the training is progressive, just as in the gymnastics and regulated and gradual exercises. I cannot recall to my mind any case of locomotor ataxia coming on in persons previously blind from other causes. My experience, of course, is very limited, but I think that statistics would show that the percentage of such is very small. If this is so, it adds a strong argument in favour of my theory. I trust that some neurologists of experience will be able to throw light on the subject and show whether the percentage just mentioned is small or not.—I am, Sirs, yours faithfully,

June 9th, 1901. EDGAR F. CYRIAX, M.B., Ch.B. Edin.

"LEGISLATION AGAINST NATIONAL INTEMPERANCE."

To the Editors of THE LANCET.

SIRS,—I have to thank my friend Dr. G. Archdall Reid for his letter published in THE LANCET of June 22nd, p. 1790. At last he makes his position clear. He founds his views on Galton not on Weismann, but the distinction is really one without a difference. Both contend for the non-transmissibility of "acquired" modifications or features. The only point of variation is that Galton arrives at his conclusion by one route, Weismann by another. Both views are pure speculations. Dr. Reid therefore bases his views, which are also speculations, on a like foundation. So far, therefore, when he contends that we who believe that acquired characters may be transmitted have no proof of our belief, he possesses no advantage over us. If one view (as a theory) is permissible, the other (as a theory) is equally so. But Dr. Reid thinks that the germ-plasm—assuming for the moment that the great divergence between germ and soma contended for by Galton and Weismann is a reality—can never be impressed by acquired characters. I ask him, therefore, in turn, how he knows this? The whole matter is one of explaining certain facts, and I may remind him that there are cases and facts which appear to be as explicable certainly on the theory of the transmission of acquired features as on that of natural selection. If any biologist will demonstrate that the germ-plasm is utterly independent of the body-plasm, then Galton's hypothesis may have a fair chance of passing into the region of demonstrated fact. As it is, I regard Darwin's "pangenetic" theory as a far more likely explanation of the reason of the germ being capable of reproducing parental features. Dr. Reid has over and over again made the assertion that naturalists have ransacked the animal and plant worlds without finding an instance of the transmission of acquired characters. He would have been more just and correct had he said that he really means that his theory is the only one that explains instances of transmission. In your own columns, Sirs, you have published cases (e.g., those of Dr. W. Duncan) which demand explanation. In *Nature* of a fortnight ago there is the case of the oysters given by Mr. J. M. Tabor. There is the case of the motmot's feathers alluded to by Darwin. There is the instance of Japanese fowls and their tail-feathers, also alluded to in *Nature* a week or two ago by Mr. J. M. Cunningham. I might multiply examples, but if Dr. Reid is in earnest in seeking material he will find no lack of such. The opinion that acquired features may be handed on is, to put the case very mildly, just as feasible an explanation of facts as the opposite view. Possibly Dr. Reid does not think the opinions of Mr. Herbert Spencer, Hertwig, Eimer, or Cunningham worth consideration; yet in biology these are names which carry weight and they are those of men opposed, on purely scientific considerations, to the idea that acquired features are never transmissible and that this view can explain no fact of inheritance. The long and the short of it is that Dr. Reid and his opponents are dealing with speculations pure and simple, and the one view is just as tenable as the other. Certain it is also that the one theory is not inconsistent with the other. Both may be correct and both have to be judged by the only safe criterion of any hypothesis—namely, that a good theory explains all the facts and is contrary to none. It has not yet, at least, been demonstrated that the theory that acquired characters may be handed on by processes of heredity is inconsistent with facts.

I am, Sirs, yours faithfully,

Edinburgh, June 22nd, 1901. ANDREW WILSON.

"THE SURGERY OF PREGNANCY AND LABOUR COMPLICATED WITH TUMOURS."

To the Editors of THE LANCET.

SIRS,—I have read with much interest the letters of Dr. G. E. Herman and Mr. Bland-Sutton and Dr. W. S. Playfair in THE LANCET of Feb. 16th and 23rd. Apart from any possible chance of being misunderstood may I add my contribution of opinion to those already expressed? The times are changed, but have the members of the profession who teach and practise gynæcology changed with them? If anyone interested will refer to Dr. Spencer's paper in the *British Medical Journal*, No. 1720, p. 1315, he will find an excellent then up-to-date account of the advantages attending the practice of obstetric physicians who performed major abdominal surgery. It is curious that a sort of general statement which appeared in the *Gynæcological Journal*, vol. ix., 1894, pp. 451–454, has left very little for anyone to add. Still, as in 1893, "Bartholomew's blocks the way." It is true that, fortunately, neither the reputation of the great hospital nor the sick poor suffer, as in the hands of the very competent staff the work done in abdominal surgery and gynæcology ranks with any other London hospital. In the excellent hospitals of Australasia and New Zealand are many gynæcologists, some of whom are physicians and some surgeons, who are worthy to be ranked with some of their brethren who are now in London, Liverpool, Manchester, and other large cities. So ere we decide one way or the other it is well to have all the facts clearly before us. May I add that I claim to practise what I teach—viz., the very great importance of always endeavouring to make a clear diagnosis before deciding to operate? True, the best men may make mistakes, but he who is "never wrong" has yet to be found.

During the past 20 or 25 years no branch of medical practice has made such great advances as gynæcology. This being granted, is it not natural that there may also exist certain differences of opinion between gentlemen who may have been influenced by their individual experiences and opportunities? For example, some operators are, as a matter of individual experience, advocates of the vaginal rather than the abdominal route for entering the peritoneal cavity. Some prefer to attack diseased renal organs from an incision directly over the kidney, others prefer generally to operate by opening the peritoneal cavity as in abdominal section. Some have, perhaps, abused oöphorectomy and not unfrequently removed one if not both healthy ovaries. At best the patient has to depend on the skill and experience of the gynæcologist whom she may be under, and on his part the operator must treat every case of pregnancy complicated by tumour upon no fixed operative basis but as the peculiar or special circumstances seem to require. No general rule will be found applicable to all cases of pregnancy complicated by a tumour.

I am, Sirs, yours faithfully,
A. D. Leith Napier.
Adelaide, S.A.

THE CASE OF SURGEON W. R. KNIGHTLEY, R.N.

To the Editors of The Lancet.

Sirs,—I beg to bring to your notice the action of the General Medical Council and the naval medical officer. To abuse the relationship between medical adviser and patient is most reprehensible, but I thought it was a maxim of English law that a subject should not be punished twice for the same offence. To mulct a man in £3000 damages in a civil court and then for the General Medical Council to take away his means of gaining a livelihood is to my mind certainly not justice tempered with mercy.

I am, Sirs, yours faithfully,
Fredk. W. Collingwood.
Wimpole-street, W., June 24th, 1901.

To the Editors of The Lancet.

Sirs,—The proceedings of the General Medical Council are always read with great interest. One turns, after the labours of the week, to the report in The Lancet with eagerness to note what progress has been made, and how that august body are upholding the honour and dignity of the profession. After the tremendous slap in the face administered to them by Mr. Chamberlain in the case of Dr. Irvine I really thought they would be more guarded as to the course they adopted towards any other sinner who might be so unfortunate as to come under censure, particularly a man holding a position in the navy and so more or less under the ægis and protection of the Government. But it appears that the General Medical Council are bent upon riding for a fall. I deduce this from the extraordinary decision arrived at in the case of Surgeon W. R. Knightley. Anything more unjust, oppressive, and arbitrary can hardly be imagined, and I am astonished at such unfair treatment, so vindictive and opposed to the principles of English law. However guilty the man was he has paid the penalty and should not be tried again for the same offence. A certain punishment has been meted out to him and the infliction of this ought certainly to have condoned the matter. The jury arrived at a decision and awarded a fine they considered would be sufficient penalty, but if that jury had known that as a consequence of their verdict the man's livelihood would be taken from him and that his pecuniary loss would far exceed the sum they in their wisdom fixed upon I am certain the amount would have been put at a far less sum. If the naval authorities take the same view of the matter it only remains for them to keep Surgeon Knightley in his position as surgeon on board H.M.S. *Harrier*. He may snap his fingers in the faces of the General Medical Council and they will be powerless to resent it. It is certainly time the profession had more Direct Representatives and both services should be represented on the Council, which is composed too much of teachers and consultants.

I am, Sirs, yours faithfully,
M.D.

⁂ We do not agree with our correspondents' strictures on the General Medical Council in this matter. It must be remembered that when a medical man abuses the position which his profession gives him by seducing a female patient he inflicts a terrible blow upon the honour of his calling—that very honour which the General Medical Council should be alert to maintain. Still, it is true that if the jury had realised the heavy penalty that the disciplinary body of the medical profession might later exact from Surgeon Knightley it is possible that they would have awarded less damages to the injured husband. We believe, however, that from a legal point of view damages are awarded as a *solatium* to the husband for his loss and not as a punishment to the person who deprives him of his wife. We do not think the naval authorities will be well advised to ignore Surgeon-Knightley's position. All candidates for commission in the naval medical service are required to be "registered under the Medical Acts in force," and it would be inconsistent to ask less from an officer with a commission than is demanded from those who aspire to a commission.—Ed. L.

"SUGAR-FREE MILK AS A FOOD FOR DIABETICS."

To the Editors of The Lancet.

Sirs,—I have read with great interest Dr. Robert Hutchison's article which appeared last week in The Lancet, advocating the use of a sugar-free milk as a food for diabetics. Dr. Hutchison removes the sugar from the milk by curdling with acetic acid and subsequently washing the curd. He then dissolves the casein in a little potash, afterwards adding cream and a little gelatin and saccharin. The product is then strained. It seems to me that this plan of preparation is unnecessarily elaborate in view of the fact that pure soluble casein is a commercial product. My firm, for example, make tons of perfectly pure casein from the best quality of English milk in the form of a fine white powder, perfectly soluble in water. In contains nearly 90 per cent. of casein along with milk salts. It is practically tasteless, and very cheap. Surely it would be simpler to use this casein directly instead of milk, dissolving a definite quantity in water and adding cream, gelatin, and a little saccharin in the manner suggested by Dr. Hutchison.

I am, Sirs, yours very truly,
Chas. Prideaux.
Motcombe, Dorset.

"HOSPITAL SUNDAY AND THE NATIONAL ANTI-VIVISECTION SOCIETY."

To the Editors of The Lancet.

Sirs,—Although in your attack upon me in The Lancet of June 22nd, p. 1771, you say of me "he may spare himself the trouble of writing two-column letters to us," I presume that you will allow me a modest corner in your paper for a few words in defence of myself. You say "the hospital authorities have a perfect right to subsidise their schools if they like." If that be so, why have we not an equal right to inform the public that they do so?

Our position is a perfectly proper one. We assert (1) that congregations on Hospital Sunday are asked to subscribe for the tending of the sick poor, and in the vast majority of churches are not informed that the education of medical students will in part be defrayed out of the funds into which their contributions are paid; (2) that as a fact the Mansion House Fund does pay the money so subscribed in the churches into the general funds of hospitals out of which general funds the subsidies to the schools are made; (3) that the clergy can ascertain these facts for themselves if they look at the published accounts of the hospitals; and (4) that it is quite unfair to hide these facts from those who give the money, and that if the clergy will not communicate them we are absolutely justified in taking the only means left us of imparting a knowledge of them to the congregations.

Next let me say that as regards the single specific inaccuracy you think you have discovered in my "Guide to the Charitable," the returns for 1899 were the last available when the last edition of the Guide was printed, and those returns contained Dr. C. Arkle's name in the relation to Charing Cross Hospital which the guide records. If Dr. Arkle be now, as you say, dead, the next edition corrected with the returns of 1900 (only recently published) will be as accurate as was the last. Lastly, I hope I may explain that I myself, and I imagine most reasonable anti-vivisectionists, would not refuse as a matter of conscience a benefit that might be assigned as to its discovery to vivisection. We need not refuse to use a drug because some industrious but irrelevant experiments have been made with it upon animals. We need not accept the hypothesis that the best way to find out the internal construction of an apple is to cut open an orange. And were all the extravagant claims of the vivisectors true, we are no more morally bound to reject benefits acquired by indefensible means than are the descendants of slave-holders bound to abandon wealth originally acquired by the detestable abomination of slavery.

I am, Sirs, yours faithfully,
Stephen Coleridge.
June 22nd, 1901.

METROPOLITAN HOSPITAL SUNDAY FUND.

The following is a continued record of some of the principal amounts that have been received in aid of the Fund up to the time of going to press on Thursday. The total sum then amounted to £36,000. At the corresponding period last year the total was £31,000:—

	£	s.	d.
Christ Church, Lancaster-gate (including additions) ...	1317	0	0
St. Michael's, Chester square (including an additional £5)	1233	0	0
St. Jude's, South Kensington	557	0	0
St. Paul's, Onslow-square	360	0	0
St. Paul's, Knightsbridge, with St. Mary's, Graham-street	291	0	0
St. George's, Hanover-square	252	0	0
St. Marylebone Parish Church	209	0	0

THE ROYAL UNIVERSITY OF IRELAND COMMISSION.

(From a Correspondent.)

After a long delay Mr. Arthur Balfour announced on June 20th to the House of Commons the names of the Commissioners, as well as the terms of reference, and from the criticism aroused in Ireland it is becoming apparent that this Commission, like so many similar inquiries, may only end in failure. In the first place, the terms of reference "to inquire into the present position of higher, general, and technical education outside Trinity College, Dublin, and to report as to what reforms, if any, are desirable in order to render that education adequate to the needs of the Irish people," are very peculiar. Imagine a Commission to inquire into higher education in England "outside Oxford and Cambridge," or of Scotland "outside Edinburgh University." It is, indeed, the play of *Hamlet* with Hamlet left out. This leaving out of Trinity College has caused intense indignation among the northern Presbyterians; it has failed to satisfy the Roman Catholics; a large number of the younger Trinity College men, who lament the rapidly falling number of their students, object to the exclusion of their College, as they hoped that evidence given before the Commission would have led to reforms and changes suited to the present age; and all true educationists feel that the recommendations of a Royal Commission on Irish University Education which excludes Trinity College will not be worth the paper on which they are printed. Then comes the practical question, Is the chairman (a Scots lawyer) at once to closure any witness who makes the slightest reference to Trinity College? When the Royal University of Ireland was established in the place of the Queen's University the following clause in the Act establishing it was passed:—

> In fixing the value and the number of the said several exhibitions, [illegible] the Senate shall have regard [illegible] the University of Dublin [illegible] in that University, to as

to avoid, as far as possible, any injury to the advancement of learning in that University and College.

This most remarkable provision really means that the education and the encouragement of education of five-sixths of the Irish people should be regulated by consideration for the privileges of Trinity College. How, then, can the Commissioners form any idea of the influence of this provision on the education of five-sixths of the people of Ireland without a knowledge of the finances of Trinity? Again, what does "general and technical education" mean? It is surely broad enough to include education of every description, and at the present moment is not the whole empire calling out for teaching of technical and commercial subjects? and yet there is not a single member of this Royal Commission with any special knowledge of either commercial or technical education. Then the constitution of the Commission is most extraordinary. Trinity College is to be carefully excluded from discussion, and yet the Vice-Chancellor of Dublin University (Mr. Justice Madden) and a Fellow and Tutor of Trinity College and a present member of the academic council of Dublin University (Mr. W. J. M. Starkie) are put on the Commission, in order apparently at once to prevent any chance reference which might be made to that College. It will be remembered that in addition to the large number of Royal University graduates there are also many old Queen's University men, and yet one of the most unfair features of this remarkable Commission is that among the 12 members there is not one to represent the graduates of the old Queen's or of the present Royal University graduates. As is well known to the public there is a marked cleavage of opinion in the Senate of the Royal University on the question of the solution of the Irish University problem. Two of the senators—Mr. Starkie (a Roman Catholic) and the Roman Catholic Bishop of Clonfert—both of them declared opponents of non-denominational education and of the Queen's Colleges are appointed members of this Commission, and not one single representative of those on the Senate who advocate the non-sectarian view of education has been selected. The method in which the various faculties are represented is also most peculiar. Literature is represented by seven members; law by two, including the chairman; general science by two; and medicine by one. The gentleman who is the medical commissioner is an examiner in the Royal University and he may find himself in an unenviable position, sitting in judgment, perhaps, on his colleagues. In appointing a Commission the Government might have adopted one of two courses; first, they could have selected men of recognised position in the educational world outside Ireland altogether, who had never committed themselves on this most vexed question, or they might have appointed a Commission with the various contending opinions fairly represented. They have taken neither course, but have appointed a Commission of whom it is openly stated in the Irish newspaper press that seven out of the twelve Commissioners are already pledged to a definite settlement of Irish University education before they have heard one word of evidence. It is, indeed, amusing to read the opinions of many of the Commissioners—in former public utterances—quoted now in the newspapers. On the other hand, the Government has made the serious mistake of appointing no representative of those who hold strong views on the subject. I have carefully avoided expressing any opinion as to what the final solution of Irish University education should be. One hoped to get light and truth out of the evidence presented by those examined at this Commission, but it is apparent that no solution of this admittedly thorny problem worth considering can be hoped for from a Commission on which the views of large numbers of the citizens of Ireland are not represented.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

The Decline of the Plague Epidemic.—The Escape of Rangoon.—Treatment of Plague in Bombay.—Relapsing Fever in Bombay.—Establishment of a Dental Surgery at Quetta.—Privilege Leave for China Officers.—Prosecution for Adulteration.—The Culpable Negligence of Native Chiefs during the Famine.

THE epidemic of plague throughout India continues to decline although this week's figures are larger by the inclusion of deaths in the Punjab which ought to have been returned in May. The deaths are rapidly going down in Bombay city and in the Presidency and at Karachi the outbreak has nearly subsided. At most other places previously affected there is a decline also, but in Belgaum the deaths have increased from 116 to 181 and I hear that several cases have unexpectedly occurred in Poona. This is ominous because it was at this period of the year that the previous severe recrudescence occurred in Poona. Calcutta is by no means free but the daily returns have come down to single figures.

I hear that a few weeks ago Rangoon had a very narrow escape of becoming infected. A coolie of low caste was permitted to land and to go to his destination, but the next day he was found with high fever and was removed to hospital with undoubted plague but he died on the following day. Apparently he has not left any infection behind him and Rangoon may be said to have had a lucky escape. The case, if correctly reported, suggests that sufficient care was not exercised in his examination, as at the time plague was raging severely in Calcutta and special precautions should have been taken on his arrival. I understand that a great display of police force accompanies the visits of the port health officer at his inspections, which is said to have a terrorising effect upon the native passengers. This was not formerly considered necessary, and if not really required is on several grounds undesirable.

A plan of treatment for plague now being advocated in Bombay consists in the internal administration of iodine terchloride. The chief enthusiast for this treatment publishes figures showing a recovery rate of 58·9 per cent. The experiments do not seem to have been carried out under scientific conditions.

A return issued by the accountant to the Corporation of Bombay shows the total plague expenditure for that city at over 50 lakhs of rupees. Relapsing fever continues rife in the city, where it has been regularly in existence since 1897. The type of the disease is said to have become more severe, and whereas formerly the mortality was between 10 and 20 per cent. it has now reached 50 per cent. I doubt this.

Government have sanctioned as an experiment the establishment of a dental surgery at Quetta for the benefit of British troops and also sanctioned a grant of 100 rupees a month for the purchase of materials.

90 days' privilege leave is sanctioned to all officers and subordinates, subject to military rules, reverting from field service in China. Such leave must be taken within a year, and it may be taken either from China or subsequently from India.

A very interesting case of prosecution for adulteration has recently occurred in Calcutta. A large ghee (clarified butter) merchant was convicted and fined. The evidence of Dr. Bedford was cited against that of Dr. Dutt, the municipal analyst, and the magistrate found practically that Dr. Bedford's analysis was not based on any accepted standard, and held that several of his conclusions were valueless. The judgment was a clever piece of dissection of scientific evidence.

The culpable negligence of certain native chiefs with regard to famine has been shown in the two states of Bundi and Indore. The agent in Rajputana wrote: "The Bundi durbar are slack and apathetic—they regard the mortality as inevitable." The people suffered terribly. The census showed that in 10 years the population in Bundi has decreased 42 per cent. Famine is mainly responsible for this, and the culpable neglect on the part of the chief and his durbar had much to account for the mortality. Again, in Indore the Maharajah himself peremptorily ordered the stoppage of all famine relief and further declined to permit any suspension of revenue. At the time his subjects were dying by hundreds and there was plenty of money in the treasury. After the mischief had been done His Highness yielded. The conduct of these two rulers was, to say the least, apathetic and discreditable to native rule. Fortunately, these two cases are exceptional.

June 8th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Banquet to Local Civil Surgeons who have served in South Africa.

MR. F. M. Aldred, Dr. T. T. Bark, Mr. W. B. Bennett, Dr. R. Craig Dun, Mr. A. M. Dodd, Dr. Arthur Evans, Mr. T. H. Moyles, Mr. J. Owen, Mr. E.

Roberts, Dr Arthur N Walker, and Dr J H Willett, who have served as civil surgeons with the forces in South Africa, were entertained to dinner at the Exchange Station Hotel on June 20th as a professional recognition of their services The chair was occupied by Mr Edgar A Browne, the President of the Liverpool Medical Institution, Sir William Mitchell Banks occupying the vice-chair The chairman, in proposing the health of "The Guests," paid a fitting tribute to their patriotism and self sacrifice and made a touching allusion to the late Mr. Edgar Smith who had succumbed to enteric fever The feature of the entertainment was the remarkable speech of Dr R Craig Dun, late of the 2nd Battalion of the Imperial Yeomanry, in reply to the toast of "The Guests" The gist of Dr Dun's speech was practically a vindication of Mr Burdett Coutts's charges of the breakdown of the Army Medical Department, which he attributed to "army regulations,' and not to any shortcomings on the part of the Royal Army Medical Corps who had done splendid work under the greatest possible difficulties In the face of the existing regulations he could not honestly advise any graduate in medicine to look to service in the army as a fair field for his energies There was great bustle among the hospitals in South Africa when it was known that the Commission was coming out He must say that the Commissioners were considerate—they always gave a hospital 48 hours' notice of their approaching visit The impression left among medical men at the front was that the Commission was "a roaring farce" But it was not The Commission came home and whitewashed the whole thing, and quite rightly It would have been a mistake for the public to have believed that everything Mr Burdett-Coutts said was true though it was true for all that In conclusion Dr Dun said that at present promotions in the Royal Army Medical Corps depended, not upon professional ability, but upon a man filling in his *return sheets accurately* The medical men at the front spent a great deal of their time in filling up return sheets He would relegate this clerical work to non commissioned officers He advocated a return to the older system of regimental surgeons as far preferable to the existing arrangements He also severely criticised the want of medical equipment for his corps at critical times Altogether Dr Dun does not appear to have been impressed with the fore thought of the army authorities

Hospital Saturday Fund Street Collection

The result of the street collection made by the ladies on behalf of the Hospital Saturday Fund on June 8th was disappointing The collection only realised £781 18*s* 4½*d*, as against £837 12*s* 4*d* last year It was fully expected that at least £1000 would have been obtained, as the weather was exceptionally favourable for the collection

Low Death rate in Liverpool

Dr E W Hope, the medical officer of health, had the satisfaction to inform the health committee that the death rate for the week ending June 15th was only 18 5 per 1000 of the population

The Birkenhead Guardians and Lady Doctors

The Birkenhead guardians have been accused of lack of chivalrous conduct towards the female sex by their recent action in the matter of the vacancy for the post of assistant medical officer to the Birkenhead workhouse hospital In reply to an advertisement inviting candidates to apply for the post two qualified ladies responded, both of whom were requested to attend the meeting of the board A male candidate was also invited to attend, but failed to do so leaving the two ladies in possession of the field Mr T R Bulley moved the appointment of Miss Eva M Call M B Glasg, one of the lady applicants, which was duly seconded An amendment was moved by Mr H Pooley

> That, as there had not been a large response to the board's advertisement, another advertisement should be issued and that the salary offered now should be £130 instead of £120 per annum.

He did not think the position was one for a woman, as the strain was very great and there were cases in the place with which a woman ought not to deal This amendment was carried by the casting vote of the chairman, with the result that an advertisement now appears in the medical press inviting applications for the post of "male assistant medical officer" It will be generally conceded that a male resident medical officer is more suitable for the appointment in question, but there can be no difference of opinion that the lady candidates have reason to complain of the action of the authorities in inviting them to apply for a post for which half the board considered them unsuitable The arguments adduced at the meeting ought to have been thrashed out prior to issuing the first advertisement—the ladies would not then have been placed in such a false position The action of the guardians was severely criticised by the local press, and deservedly so As a solace to the feelings of the lady candidates Mr Pooley was good enough to remark that "when the time arrived for appointing two doctors he would support the appointment of a woman for the female patients only '

A Mortuary for Birkenhead

An inquiry was held at the Birkenhead Town Hall on June 20th by Dr E P Manby, Local Government Board inspector, into an application by the Birkenhead corporation for powers to borrow £750 for the purpose of erecting a mortuary Evidence was adduced as to the necessity for the provision of a properly equipped mortuary by the borough coroner and several corporation officials It is satisfactory to find that the inspector was thoroughly in sympathy with the corporation and remarked that there was no doubt that a mortuary was needed in the borough

Liverpool Country Hospital for Chronic Diseases in Children

In March last an announcement was made by the chairman at the annual meeting of the subscribers to the Liverpool Country Hospital that a gentleman who desired to remain anonymous had made a generous offer to contribute £5000 towards the funds for the new hospital, which is to be erected at Heswall, at a cost of £20 000 The offer was conditional upon three other donations of a similar amount being forthcoming by June 30th The committee have endeavoured to comply with the condition imposed by the anonymous donor, but as yet the contributions have not reached the amount stipulated During the past three months £5000 in various sums have been promised The calls made upon the charitably disposed within the last few years for various philanthropic objects have been very great At the present time the appeal by the bishop of the diocese for funds to erect a cathedral has met with a response of £138 000 within a very short time and the fund presided over by the Lord Mayor for the erection of a memorial to her late Gracious Majesty has also been liberally responded to These calls upon the public liberality are likely to affect the hospitals, at the same time, it would be unfortunate if the generous offer to the Liverpool Children's Country Hospital were to lapse through non compliance with the stipulated conditions

The Maghull Epileptic Home Munificent Offer by Mr Alfred L Jones

The twelfth annual report of the committee stated that during the year 1900 81 males and 66 females were admitted, 21 patients had been discharged, and three had died, and on Dec 31st there remained in the home 69 males and 54 females *Land had been purchased for the purpose of* erecting a villa for first class patients and to provide accommodation for the nursing staff of the male department The building, roads and drainage were estimated to cost £5500 towards which the committee had funds in hand or promised amounting to £3500 leaving £2000 still to be provided A friend had generously promised £500 towards the cost of furnishing the villa, and another friend had intimated her willingness to furnish a suite of rooms A further expenditure of £360 would be involved in carrying out certain sanitary improvements Mr Alfred L Jones, in moving the adoption of the treasurer's statement, said that he felt the greatest sympathy with the efforts put forward by the committee, and he believed they wanted something like £10 000 to carry out the work properly He would consider it a very great pleasure if he were allowed to contribute £1000 provided they got the whole sum required within six months from the date of his offer If the response did not come he would willingly give half the amount The medical report is very satisfactory, but *it points out that* there were in the home epileptics who could plough, hoe, reap, milk cows make baskets, wash, iron, and cook—in fact, the homes were blocked by these trained cases who occupied the ground necessary for developing the faculties of the new patients It was worse than useless discharging them to their friends who could not find them employment

New Nurses' Home at St Helens

The new home for the district nurses of St Helens, the generous gift of Mr. and Mrs. W. W. Pilkington, was formally inaugurated on June 19th. The house, which is a most suitable one, was built by the late Mr. James Hill who left a legacy of £150 to the charity. There is ample room to increase the staff of nurses when the funds permit. In March last the institution was affiliated with the Queen Victoria Jubilee Institute, which it is expected will increase the efficiency of the work. The staff now consists of a sister superintendent and three fully-trained nurses. The rules are on the lines of the Queen Victoria Jubilee Institute. Three members of the Medical Society of St. Helens have been nominated as members of the committee.

June 25th.

WALES AND WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

The Disinfection of Midwives.

IN many parts of Wales the woman who lays out the dead also follows the business of midwife, a combination of duties hardly conducive to the speedy recovery of the occupant of the lying-in room. Mr. G. H. Browne, the medical officer of health of Brynmawr, reports a case in which a woman died from puerperal fever; the clothes of the midwife were disinfected, but she subsequently laid out the dead body of her patient, thus re-infecting herself, and then attended and infected another woman. In at least one of the large urban districts in Glamorgan, upon a case of puerperal fever being reported, the ambulance is sent for the midwife in attendance and she is required not only to have her clothes passed through the steam disinfector but also to have a bath in the discharging block of the district hospital under the direct supervision of a nurse who sees that the woman's hands and arms are well soaked in a solution of perchloride of mercury.

A Coroner's Censure of a Quack.

The number of uncertified deaths in the colliery districts of South Wales compares favourably with the rest of England and Wales, and very favourably indeed with certain districts in the county of Durham and in other parts of the North of England. During 1900 only 1·1 per cent. of the total deaths were uncertified in the Rhondda Valley, 0·7 per cent. in Merthyr, and 0·5 per cent. in Aberdare, while in Jarrow the percentage was 5·3, and in South Shields it was 4·3. It must not be supposed, however, that either the quack or the bone-setter are unknown in South Wales. Occasionally they are very much in evidence and only narrowly escape being committed for manslaughter by a coroner's jury. Such an instance occurred recently at Ebbw Vale where an inquest was held upon a child, aged two years, who had died four weeks after receiving an injury to its leg. For about three weeks after the injury a local surgeon attended the child and he considered that it was progressing towards recovery. The child's father, however, was of a contrary opinion and consulted a man who, besides being a puddler and a painter, had inherited from his aunt a receipt for a "salve" which was said to be made of "olive oil, ground ivy, and elder leaf," but which was found upon examination to contain also sulphate of iron with traces of copper and lead ingredients which the puddler was unable to account for. A plaster of this unguent was placed over a small ulcer on the child's leg, and after a few days it died in a convulsion. Upon post-mortem examination the kidneys were found to be diseased and to this cause death was attributed. The coroner, in his direction to the jury, spoke in strong terms of the ignorant, conceited old quack whose only qualification was that he was a puddler and a painter, and whose ignorance in undertaking to treat a case requiring medical skill made him liable to be committed for manslaughter.

The Bath Guardians and Tuberculosis.

One of the most gratifying features in the crusade against tuberculosis is the desire which is being shown by boards of guardians to deal specially with cases of this disease both in the workhouses and among persons receiving outdoor relief. The Bath board recently appointed a special sub-committee to consider what steps should be taken in this direction and the report of the committee was presented to the board on June 19th. There are, it appears, at the present time seven patients suffering from pulmonary tuberculosis in the Bath workhouse and 22 others are in receipt of outdoor relief. The committee recommend that certain wards should be set apart for the isolation of the indoor cases and that a piece of land upon which shelters could be erected should be devoted to their use for open-air treatment. The board decided to discuss at a future date the committee's recommendations, which can hardly be characterised as extravagant, and there ought to be no difficulty in securing their adoption.

Homes for Inebriates.

The Glamorgan County Council have decided not to erect for the present a home for inebriates in the county but to make use of the institution about to be established by the Northampton County Council who will be paid for each patient received from Glamorgan the sum of 10*s.* 6*d.* in addition to the Government grant.

Isolation Hospital for Llandaff and Dinas Powis.

One portion of the Llandaff and Dinas Powis Rural Sanitary District adjoins the borough of Cardiff and another portion is close to Barry. Indeed, to a certain extent the rural district is sandwiched between these two towns, each of which possesses a well-equipped isolation hospital which might very well serve the needs of the rural district. For the past few years the Cardiff corporation have been willing to receive patients from the Llandaff district into the Cardiff sanatorium, but only at what was considered by the Llandaff Rural District Council the exorbitant charge of two guineas per patient weekly. Three months ago, therefore, the Llandaff council erected within their own district at a cost of £800 an iron hospital with accommodation for 10 patients, and they have further decided to expend the sum of £8500 upon permanent buildings. These will include an administrative block, laundry and disinfecting block, and two ward pavilions—one to accommodate 10 and the other four patients. When the scheme is completed there will thus be accommodation for 24 patients and it will be possible to treat three diseases simultaneously. The population of the rural district of Llandaff in 1891 was 18,539, with an average of five persons in each inhabited house; at the last census the population was 23,054, with an average of 4·8 persons per house.

The Bristol Guardians and the Home for Cripples.

For some years past the Bristol Board of Guardians has sent to the Orthopædic Hospital and Cripples' Home at Redlands a certain number of pauper children, for whom it was considered that the special treatment of the hospital would be beneficial. At the present time there are 13 of these children in the institution. The guardians have hitherto paid £13 yearly for each child, although the cost to the hospital has actually been £28. Upon an appeal from the hospital committee the payment has been increased to £20 per annum, an amount which has received the sanction of the Local Government Board.

Convalescent Home for Children at Weston super-Mare.

The annual meeting of the subscribers to the Weston-super-Mare Convalescent Home for Children was held on June 17th, when it was reported that during 1900 there were received into the institution 280 ailing children, of whom all but five returned to their homes either perfectly well or very considerably improved in health. The accounts of the home show that the adverse balance of £64 at the end of 1899 had increased to £125 at the end of 1900.

Wonford House Hospital for the Insane, near Exeter.

This institution celebrates its centenary this year. When it was opened on July 1st, 1801, there were, besides Bethlem Hospital and St. Luke's Hospital in London, only three public asylums in England—viz., the Manchester Lunatic Asylum the York Lunatic Hospital, and the Friends' Retreat in York. The annual report for 1900, which has just been issued, states that from July 1st, 1801, to Dec. 31st, 1900, there had been 2835 patients admitted, of whom 1245 had been discharged recovered and about 700 as relieved. During 1900 there were 167 patients admitted, the daily average number in the house being 131. The Commissioners in Lunacy in their report dated July 26th, 1900, mention that "the cost of maintenance in the hospital is £2 2*s.* 11*d.* weekly, and 65 of the patients pay less than these costs and 70 over it." The report goes on to say, "This hospital continues to do really charitable work and as long as this is the case we hope it will flourish more and more."

June 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Glasgow University.

THE University has settled down again to its usual routine after the excitement of the public celebrations A steadying influence on a large number of the medical students is the impending ordeal of the final examinations which will occupy the next three weeks or so The June meeting of the University Court was mainly occupied by matters of no great interest The secretary reported that a notice of assessment for inhabited house duty on the Bute and Randolph Halls had been received, and that the Edinburgh Court had decided to appeal against a similar assessment made on the MacEwan Hall. It was decided to take joint action against the assessments. A memorial was read from the University Staff Club—which consists of some of the professors, lecturers, and assistants—requesting the establishment in the University of a common room where members of the staff might meet for various purposes. After some discussion the memorial was remitted to the committee in charge of the question of University extension. The Rev. Professor Stewart, D D., has been appointed to represent the University on the Carnegie University Trust.

Glasgow Western Infirmary.

The directors have issued an appeal for funds to enable them to proceed with the erection and equipment of a new out-patient department. The matter has been urgent for some time, but in view of other claims on the public it has not been pressed. The interests alike of the staff, the medical school, and the patients do not, however, permit of further postponement. The sum required is £40,000, towards which subscriptions amounting to £20,000 have already been received, including £5000 from the Bellahouston trustees and £1000 from the Corporation of Glasgow. It is intended to provide the new dispensary with every equipment needed for the treatment of patients and for the clinical instruction of students.

Glasgow Water-supply.

Glasgow has for many years had reason to be proud of a water supply which has brought to the city so many sanitary and commercial advantages. The enterprise and public spirit which nearly 50 years ago secured an abundant supply of pure water from Loch Katrine was recognised by the opening of the works by Her late Majesty Queen Victoria It was no doubt at that time believed that ample provision had been made, not only for present wants, but also to meet the reasonable probabilities of the future. The Act of Parliament under which the Corporation of 1855 proceeded gave authority (1) to raise Loch Katrine four feet above its previous summer level and to draw it down three feet below this level, making seven feet in depth to which the loch could be drawn upon; (2) to take 50,000,000 gallons of water per day for the supply of the city and suburbs; and (3) to construct a line of aqueducts for conveying the water to the city—a distance of 34½ miles In 1885 the corporation deemed it advisable to obtain from Parliament more extended powers. These included permission (1) to raise Loch Katrine another five feet, thus giving a total of 12 feet free to be drawn upon; (2) to raise Loch Arklet 25 feet above its then level and to lead the water from this loch to Loch Katrine; (3) to take a further 60 000 000 gallons per day for the supply of the city and suburbs; and (4) to construct a duplicate line of aqueducts and service reservoir with lines of pipes to the city. These several undertakings have been in progress during the past 15 years and have now been brought to a successful completion. The new aqueduct is 23½ miles in length and is capable of discharging 70,000,000 gallons per day. The new reservoir has a water surface of 88 acres and a capacity of 700 000,000 gallons Added to the original reservoir this means that the two combined are capable of storing 24 days' supply at the rate of 50,000,000 gallons per day. The cost of the works has been £1,213,280 It is noteworthy that the water from Loch Katrine undergoes no filtration other than being made to pass through fine gauze netting with a view to separate coarse mechanical impurities, such as leaves, sticks, &c With a view to avoid pollution the corporation some years ago acquired at a cost of £17,000 the feuing rights of the whole drainage area of Lochs Katrine and Arklet and thus have power to prevent the erection of any houses or buildings in the district From what has been stated above it is obvious that the practical result of the works just completed is to double the water-supply of the city. Since the opening of the first aqueduct 42 years ago there has been an enormous extension of the city both in area and population For this and for a continuation of the same processes during many years it is calculated the new aqueduct and the undertakings associated with it secure a full and adequate supply of a natural water which in point of purity as well as in abundance is hardly susceptible of improvement.

The Sale of Poisons by Medical Men.

A meeting of medical practitioners was held in Glasgow on June 19th, to receive a report from the deputation recently sent to the General Medical Council in regard to the sale of poisons in open surgeries by assistants not qualified under the Pharmacy Act. It will be remembered that the Council declined to receive the deputation on the ground that it proposed to deal with questions still *sub judice* The deputation therefore had no report to make other than to repeat the decision of the Council as this was expressed in the statement made by Sir William Turner Dr. W Watson, who presided over the meeting and who was a member of the deputation, stated that the result of their action was in all respects satisfactory. They had succeeded, he considered, in getting the action of the Council into line with the law of the land and he felt certain that no charge similar to the one which gave rise to their action would ever again be brought against a member of the profession so long as he showed reasonable care in the management of his business. Professor Glaister, however, doubted if this consolatory conclusion was altogether justified The finding of the Council by no means showed that the question was finally settled, but rather indicated the probability of further developments. After some discussion it was decided to continue the committee with instructions to take action if circumstances rendered this necessary. The question was also referred to at a recent meeting of the Pharmaceutical Society in Edinburgh, when the chairman claimed that the General Medical Council had decided that any medical practitioner who habitually left an open surgery stocked with scheduled poisons in charge of an unqualified assistant was liable to be judged guilty of conduct infamous in a professional respect.

Glasgow Ophthalmic Institution.

A handsome stained-glass window has been presented to this institution by Dr. A Maitland Ramsay. At a meeting of the directors of the Glasgow Royal Infirmary and others Dr. James Kerr Love explained that the window was subscribed for by the members of Dr Ramsay's post-graduate class and was intended to express their appreciation of the good work done by Dr Ramsay In accepting the window on behalf of the directors, Mr. Hugh Brown, Chairman of the Ophthalmic Committee, thanked Dr. Ramsay for his gift and for the extended sphere of usefulness which the Ophthalmic Institution had acquired as a result of the post graduate courses which have been given during the past few winters.

IRELAND.

(FROM OUR OWN CORRESPONDENTS)

National Association for the Prevention of Consumption and other Forms of Tuberculosis.

A MEETING of the executive committee of the Dublin branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis was recently held at the house of the Royal College of Physicians of Ireland Dr Lombe Atthill occupied the chair and there were also present Sir Christopher Nixon, Sir John William Moore Sir Charles Cameron, Professor Anthony Roche, Dr Alfred R Parsons, Mr F P. Fawcett, Dr Edmond J. McWeeney, Dr. James Craig, and Mr. J Knox Denham, honorary secretary The honorary secretary reported that the Local Government Board for Ireland had consented to have the large poster entitled "Information for Consumptive People and for Those who Live with Them" hung up in every workhouse, hospital, and dispensary waiting-room in Ireland Dr. Starkie, the Resident Commissioner of National Education for Ireland, had informed the honorary secretary that he would afford every facility for the giving of the course of lectures proposed by the association to be delivered to the King's scholars in the training colleges at Drumcondra, Marlborough-street, Kildare-street, and Baggot street. The names of the following gentlemen were suggested as lecturers to the King's scholars in the autumn: Dr. McWeeney, Dr. Craig, Dr. Parsons, and Professor Roche.

An Action for Damages.

It may interest some of the readers of THE LANCET to know that the action for damages brought by the son of the late Mr. Wheeler of Dublin, the well-known surgeon, against the Commissioners of Public Works in Ireland has been decided in his favour after appeal. It is now over a year since Mr. Wheeler's eye was seriously injured by an accident caused as alleged by the imperfect state of the ornamental iron railings in St. Stephen's Green Park. The commissioners pleaded that they were not the owners of the park and therefore were not liable. The Court of Queen's Bench decided against them and now after a delay of a year the Lords Justices of Appeal have by a majority supported that decision. The case is looked upon in Dublin as one of much interest and importance, and arrangements are now being made for an ultimate appeal to the House of Lords.

Royal Colleges of Physicians and Surgeons in Ireland.

A public announcement has appeared stating that material changes have been made in the course for the preliminary examination for the year 1902.

Armagh Sewerage.

At a special meeting of the Armagh Urban Council, held on June 19th, Mr. Kaye-Parry, consulting engineer, showed and explained sketch plans for a scheme for the treatment of 90 gallons of sewage per head per diem. The estimated cost was £4500, and adding £500 for a storm-water filter, the total cost of the works would be £5000 In this way they would have a scheme capable of treating three times as much as the former scheme which was only able to cope with 30 gallons of sewage matter per head per diem, while the English Local Government Board had laid it down that any disposal works should have as their minimum a capacity for the treatment of 90 gallons per head per diem, because 30 gallons was the average dry-weather flow, but in wet weather the flow was sometimes equal to as much as 100 gallons per head per diem; thus, any works the maximum capacity of which was 30 gallons would be quite inadequate. The Armagh Urban Council approved of this scheme and requested Mr. Kaye-Parry to prepare the plans as soon as possible.

Overcrowding in the Londonderry Asylum.

At a meeting of the committee of management of the Londonderry Asylum, held on June 21st, a report was received from the architect and medical superintendent in reference to their visit to Scotland to acquire information as to the selection of buildings and arrangements most likely to be suitable for the proposed extensions at Gransha. In reference to present wants, and with a view to future economy, the following schemes were suggested: (1) to build the two hospitals and infirmaries for male and female patients, 100 of each, and to use what would be the future female side for administration; (2) to build the male hospital and infirmary for 100 patients each, one of the villas to be used at present for administration; and (3) to build the male hospital and infirmary for 100 patients to the future administrative block of the asylum, and the parts of the administrative block not at present required for administrative purposes could be used for the temporary accommodation of a few more male patients. No. 1 scheme was recommended. The matter is to come up for consideration at the next meeting, some of the members being in favour of No. 1 scheme, while others think that the building should be deferred until after the consideration of the Local Government Board's recent circular anent workhouses.

Treatment of Chronic Harmless Lunatics.

The Limavady guardians having had under their consideration the circular issued by the Local Government Board in regard to the treatment and maintenance of chronic and harmless lunatics which was remitted to them from the Derry County Council decided at their meeting on June 24th to recommend the Asylum Committee to adopt the suggested course (No. 2) out of the difficulty, that is, to add, subject to the Lord Lieutenant's direction, by the erection of buildings less elaborate than the original ones, a new department to an existing asylum and to place it under the resident medical superintendent of that asylum. In this way a due measure of care and comfort would be preserved to the class of asylum inmates in question and at the same time the whole of the very inadequate grant in aid made by the Government in respect of all classes of the insane who are kept in immediate connexion with the county or district asylums would be retained.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Law as to Workmen's Compensation for Accidents and Medical Aid.

OF late the Chamber of Deputies have been discussing anew the law as to compensation to workmen for accidents sustained whilst at work. A committee of the Chamber have proposed some alterations in Clause 4 of the law of 1898. The clause as amended runs thus:—any workman who sustains an injury may choose his own medical attendant and his own druggist, but in that case the employer shall not be held responsible for medical expenses and for drugs, dressings, or the like, to an extent greater than a sum which shall be fixed by the *juge de paix* of the parish in which the accident happened. This sum shall be arrived at in conformity with the rates adopted by the department for medical aid, or, if such do not exist, with the fees usually ruling in the neighbourhood. Also, if the injured man refuses the medical and pharmaceutical aid offered by the employer and chooses to go to hospital, the employer shall, in addition to the hospital expenses, only pay three quarters of the daily indemnity. The employer may, in certain cases laid down in preceding paragraphs, submit for the consent of the *juge de paix* the name of a medical man who shall certify monthly as to the condition of the injured workman. M. Poulain put forward an amendment as regards the right of the workman to choose his own medical man. He demanded guarantees in favour of medical men who are now always exploited by the assurance societies. He also asked for the insertion of a clause specifying that surgical operations when necessary should be paid for by the employer. There is no doubt that surgical operations should be paid for by the employer if they are the consequences of an accident.

Cyto-diagnosis in Cerebro-spinal Fluid from Cases of Mental Disorder.

M. Leglas and M. Nageotte reported to the Hospitals Medical Society at the meeting held on June 7th that they had examined the cerebro-spinal fluid from seven cases of early dementia and had found no lymphocytes in it. A chronic alcoholic, of feeble intellect, with delusions of grandeur and epileptiform attacks, was found to give a normal fluid. A syphilitic patient, aged 36 years, who 55 days previously to the examination had had his first epileptiform attack showed no lymphocytosis. On the other hand, five patients in whom before lumbar puncture was performed general paralysis had either been definitely diagnosed or was strongly suspected showed marked lymphocytosis. M. Joffroy said that in his opinion the interesting point from the practical side was to know whether lymphocytosis existed in the early stages of general paralysis. In asylums patients were hardly ever seen at an earlier stage of the disease than that of some months. In one instance, however, he had found lymphocytosis at a very early stage before there was either ocular trouble or defect of speech upon which to found a diagnosis. M. Dupré said that he had practised lumbar puncture in eight patients. In two general paralytics the results were positive. In six others—a case of senile dementia, a case of dementia due to a central lesion, a case of very early dementia, and in three cases of melancholia with delirium—the results were negative. M. Nageotte said that ill-effects followed those operations where there was a small quantity of fluid and where the results were negative. M. Widal said that, as a rule, it was better not to take more than three, or at the very most six, cubic centimetres of fluid. After the operation the patient should lie down in bed for the rest of the day with the head low. Fine and very sharp needles should be used so as not to make a large hole in the dura mater, so that there was less chance of the fluid escaping on withdrawal of the needle. When these precautions were taken M. Widal's patients sometimes complained of a little nausea, but in the majority of cases they felt no inconvenience. M Widal thought that the smallest chronic lesion of the meninges could bring about lymphocytosis, but the *méningisme* of Dupré could be observed without lymphocytosis, as M. Widal had recently demonstrated in a case of typhoid fever.

Infantile Mortality in France.

At the meeting of the Academy of Medicine held on June 10th M. Budin gave an account of an inquiry into the above subject undertaken by M. Gillette of St Joseph and M. Ballestre. This inquiry showed that the mortality in France of infants under one year of age had attained appalling proportions In Paris the rate was 145 for every 1000 deaths; at Rouen, 254; at Lille, 294; at Dunkirk, 342; and at St Pol, 509. The mean mortality for all the towns in France was 167. As before this mortality could be remedied the cause must be known, the inquiry showed that of 1000 deaths in infants under one year of age, taking all the towns together, 389 were due to diarrhœa, 147 to pulmonary affections, 171 to congenital feeble health, 24 to tuberculosis, and 50 to contagious diseases. Diarrhœa was by far the most important factor and caused in Paris 380 deaths per 1000, while in Rouen and Nantes the rate rose to over 500 and at Troyes to 682 The monthly curve of diarrhœa mortality showed a marked rise during the hot months and a fall during the cold weather This diarrhœa, although so fatal, could be avoided by care. In the infants' department which M. Budin had started at the clinic of the faculty diarrhœa had completely disappeared This excellent result had encouraged the formation of similar departments, and at those under the care of M. Variot, M de Rothschild, and M. Dubrisay equally good results had been obtained Pulmonary affections also accounted for a very little number of infantile deaths, but instead of being in the summer their chief incidence fell in the winter Congenital feeble health could too be combated by appropriate care, and M. Budin had succeeded in greatly reducing the mortality in his wards for such cases. The whole inquiry showed that a large number of these deaths were preventable. One remarkable fact is the variation shown by different departments The rate varies from the lowest to one nearly double. If all the deaths of young children in France were added together the total would reach the enormous figure of 30,000 per annum—that is to say, 15,000 soldiers less in 20 years time. Most of these deaths could be prevented if the means indicated by the investigators were made use of.

The Drink Question

Since the passing of the new regulations on "drinks," the consumption of wine in Paris has gone up by 20 or 25 per cent It is to be feared, moreover, that the consumption of alcohol is not less than before the measures of reform were undertaken. The remission of the octroi has coincided with an extremely bountiful wine crop, and the price of wine has therefore fallen some 50 per cent. The working man, therefore, who used to drink half a litre with his meal now drinks a litre. Should prices rise his habits will have become fixed; he will not reduce his allowance and will consequently spend more than he did before the new regulations were in force. Official statistics for the first four months of 1901 show that the quantity of wine consumed is 17,000,000 hectolitres as against 10,000,000 hectolitres for the corresponding period of last year.

June 25th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

"*Typhoid Fever in Rome*"

THE Municipal Medical Officer of Health of Rome, Professor Gualdi, has published a work with the above title which is of more than local interest, dealing as it does with the incidence and etiology of a disease so universal in its distribution as typhoid fever. It appears from a careful comparison of statistics that, in spite of the great improvements which have been undoubtedly effected in the sanitation of the large cities of Italy, and especially of the city of Rome, during the last quarter of a century, no great diminution is noticeable in the prevalence of typhoid fever in any of them. No trustworthy statistics on this head are available for Rome itself previously to the year 1876, but it is probable that the proportion of cases to population in the past year is little different from what it was in those days, while compared with some of the intervening years last year's figures come out distinctly unfavourably. Taking the statistics in regard to typhoid fever in Rome subsequently to 1876 we find that a period of low mortality occurred in 1882, since which time the returns show a continual alternation of improvement and aggravation, the rises and falls each being spread over periods of several years' duration. Examining each year separately it will be seen that the disease has two seasons of maximum intensity—one in the winter and spring, during which it assumes an endemic sporadic character, and one in the summer and autumn, when it becomes endemic in type. The transition between the two, both in the rise and the fall, takes place with great regularity The maximum generally occurs in October and the minimum usually in April, the regularity of the periods of recurrence being more marked in the morbidity than in the mortality tables One looks with interest to see whether there are indications that one quarter of the city is more affected than another, but the division into wards is so artificial as to create a difficulty in arriving at any definite conclusion upon this point The incidence of the disease varies also from year to year, a ward which has escaped one season perhaps suffering heavily the next It is not possible, therefore, to speak of any particular ward as being specially liable, nor of any other as being particularly immune On the whole, over an average of years, the disease affected most severely those wards of the city in which new streets of badly constructed houses were rapidly run up during the time of the building speculation mania The influx of workmen at that period was contemporaneous with an increase in the amount of typhoid fever in the city—an increase which continued for several years (1884–89). From 1889 onwards the disease again diminished until it reached a minimum in 1897, again to recrudesce, however, and to attain another maximum in the three following years, without any special cause that is apparent. The explanation, according to Professor Gualdi, is to be found in a number of different factors, amongst others in the overcrowding of the poor in the new quarters of the town and in the importation of typhoid fever patients with the numerous workpeople who come to the surrounding Campagna at that season. The possibility of a contamination of the water-supply, to which many attributed the outbreaks, was investigated with great care, but it was found impossible to establish any such connexion. The sources, the aqueducts, the pipes, the reservoirs, and the water itself, were all minutely examined and always with negative results. It was natural that suspicion should fall upon the Acqua Paola on account of its origin (the Lake of Bracciano) and the fact that the part of the city chiefly supplied by that source—namely, the Trastevere—had a heavy contingent of typhoid fever patients. But it must be remembered that there is a traditional prejudice against this source which renders the people of that quarter averse to its use for drinking purposes The Acqua Marcia and the Acqua Vergine (Trevi) must be regarded as above suspicion for numerous reasons; nor in the various palaces, monasteries, and barracks supplied by the Acqua Felice was there any special prevalence of the disease that could lead to suspicion of that water. The reservoirs in the houses must likewise be acquitted of blame since the outbreaks did not occur in a way which such a source of infection would satisfactorily explain According to Professor Gualdi the disease may be transmitted in three different ways: (*a*) by direct contagion from sick to healthy; (*b*) by infection from food-stuffs; and (*c*) by means of the environment Direct contagion he believes to be frequent, but it occurs more often in the houses of the Campagna A brief visit to a typhoid fever patient is sufficient, he thinks, to transmit infection. The food stuffs most under suspicion are milk and vegetables, and to the former, the sale of which is in the hands of three or four monopolists in Rome who mix it, he attributes a large share in the spreading of infection. The vegetables grown locally are irrigated and washed with the water from the sewers in a restricted suburban zone between Via Nomentana and Via Tiburtina, and this, he thinks, accounts for the frequency of typhoid fever in the San Lorenzo and Nomentana quarters and on the Esquiline. Finally, some houses, the dirty and overcrowded especially, act as a hotbed for the disease, nursing its germs during each winter and sending them forth in fresh vigour every autumn, the infection being possibly in relation with some saprophytic phase in the existence of Eberth's bacillus and the germ escaping detection in its ectogenous condition. When inhaled by man in dust or ingested with food or drink its pathogenic effects are once more manifested, and the disease is again spread by direct contagion or otherwise.

June 23rd.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Immigrants Suffering from Tuberculosis not to be Admitted.

AN order of the United States Superintendent of Immigration, T. V. Powderly, declares that tuberculosis of the lungs is to be considered a "dangerous contagious disease." Heretofore immigrants having tuberculosis have been admitted unless the disease was in an advanced stage; when they were deported it was because they were apt to become public charges, the contagious nature of the disease not being considered. The new ruling makes the deportation of all persons having tuberculosis of the lungs compulsory. It will involve a more strict examination of immigrants at Ellis Island and the steamship companies will have to make examinations in Europe before accepting steerage passengers. About two months ago the Marine Hospital was asked by the Superintendent of Immigration if tuberculosis of the lungs was to be classed as a contagious disease; the ruling made was that the disease was considered a chronic contagious disease. The ruling was unsatisfactory, as if immigrants were deported under it contests might follow. The law says that an immigrant is to be deported who suffers from a "loathsome or dangerous contagious disease." Under the former ruling immigrants who had tuberculosis of the lungs had to be barred as likely to become public charges. Many were so barred, and though no contests followed it was felt that a more explicit order should be given. Hence, Commissioner Fritchie asked for a more specific statement. The ruling now submitted by the marine hospital service is that tuberculosis of the lungs is considered a dangerous contagious disease, and in accordance with that decision the Superintendent of Immigration has made his order. Dr. G. W. Stoner, head of the medical division of the Immigration Department, states that previously to this rule the percentage of reported cases of tuberculosis has been small. Heretofore, these persons have been placed in the category of contagious or chronic contagious and been referred to a special board of inquiry. As a rule the persons afflicted with this disease were deported on the ground that they were likely soon to become public charges, but many exceptions were made in favour of the sufferer if he or she had a family here who guaranteed the invalid's protection and care. Before the new ruling the board decided which invalid should be deported. This discrimination is now denied it, for deportation is made mandatory; this reduces the action of the board to a mere form. Dr. Stoner added that the majority of cases of tuberculosis came from the larger cities of Norway, Sweden, and the North Sea countries. Dr. Alvah H. Doty, the State health officer and sanitary inspector of the port, says that although the principle of the order is right he believes that it will be impossible for the health officers of this port to put it into execution Often 4000 emigrants land here in a single day; it is difficult at a glance to detect consumption except in advanced stages, and an adequate examination would therefore compel the retention of these thousands for weeks. A cursory examination, on the other hand, would be useless. He believes that cases of consumption should be kept out by examination of emigrants at the point of embarkation where the work can be done thoroughly. This method would also prevent the contact of cases of tuberculosis with other emigrants in the steerage. Dr Doty urges that the first step in the carrying-out of the new order should be taken by the inspecting officers at the great ports from which our immigrants come. While not opposed to federal regulations they do not affect him as a State officer and as such he will not attempt to bar out cases of tuberculosis. Officers of steamship lines assumed that the new order would not result in many deportations because consumptive emigrants are not allowed to embark when the disease is detected. The agent of the American line said that medical inspectors are at present so careful in their examination of emigrants sailing for this country that but few cases of tuberculosis escape them; hence the number deported from this port has been small, consumption being the cause, so that the new order will not have much significance. The rate of deportations had been considerably less than 1 per cent. At the office of the Hamburg-American line it was said that the new clause relating to the admission of immigrants of weak physique sufficiently covered those afflicted with tuberculosis. Greater precautionary methods will be observed in the inspections in Holland, but it is not likely that there will be any great reduction in the number of immigrants entering this port, owing to the enforcement of the new order. This line brings into this country about 50,000 persons a year, of whom about 800, or a little more than 1 per cent., show symptoms of consumption in the examination made at Ellis Island; most of these are Jews from Russia, Galicia, and the Balkan States. The agent insisted that the Hamburg-American line took every precaution to prevent the embarkation of cases of tuberculosis; their hospitals and physicians were intended mostly for persons not afflicted with organic diseases; it is not often that application is made to this line for transportation for a patient suffering from tuberculosis.

Government Regulation of Vice in the Philippines strongly Opposed by Women.

Through the influence brought to bear upon the authorities at Washington by women belonging to the United States Temperance Association the army canteen was abolished some time ago. This step was taken in face of the advice tendered to the contrary by army officers of all grades competent by experience to have a good knowledge of the situation. It is now declared that the action on the part of the Government has produced most unfortunate results, has led to increased drunkenness and the widespread prevalence of venereal diseases. So much, indeed, has this been the case that it is proposed that methods for the regulation of vice, somewhat on the model of the British Army Contagious Diseases Act, should be introduced into the Philippines. On June 6th, at the morning meeting of the American Medical Association in St. Paul, Minnesota, two prominent lady members of the United States National Women's Suffrage Association, Miss Susan B. Anthony and the Rev. Anna H. Shaw, protested against the proposed legislation to suppress vice in the Philippines. The Rev. Anna Shaw, in the course of her remarks, said: "When we undertake to regulate and segregate vice in the Philippines it is impossible that we shall not regulate and segregate vice at home. Under our army system parts of the forces are kept in the Philippines and part at home. Then later on they will be changed. If vice is essential in the army and has to be regulated it will have to be regulated both at home and abroad. England has tried the regulation of vice and abandoned it as unsuccessful. France regulates vice and is the most vice-ridden country in Europe." In reply to the speeches of Miss Anthony and the Rev. Anna Shaw Major Louis Seaman, an ex-surgeon in the United States Volunteers, who read a powerfully written paper at the recent meeting of American army surgeons showing that the abolition of the army canteen had been responsible for increased drunkenness and vice of every description among soldiers, urged that the suggested legislation was the best possible remedy for the existing condition of affairs and its enforcement was strongly indicated in the Philippines. When, however, Major Seaman referred to the women speakers as those misguided enthusiasts and declared that they had brought about such a condition by the results of their agitation, the uproar which ensued was so great that he was unable to proceed, and Dr. Reed, the President, prevented any further discussion by announcing the next order of business. There can be no doubt that the views set forth by Major Seaman are thoroughly endorsed by the great majority of American army surgeons. This fact was clearly demonstrated by the resolutions passed at the meeting of the army surgeons some two or three weeks ago to the effect that the meeting was in agreement with Major Seaman, and furthermore resolved that a copy of these resolutions should be sent to each member of the Women's Temperance Association, to whose efforts was due the abolition of the army canteen. It would appear, too, as if the greater number of the members of the American Medical Association sympathised with the proposed adoption of legislative measures to suppress vice in the Philippines but were to some extent restrained from giving expression to their opinions by the presence of Miss Anthony and the Rev. Anna Shaw. No action in the matter was taken by the convention, but it is probable, if the feminine influence—which carries much weight in this country—does not prove too strong, that Government regulation of vice will be put into practice in the Philippines.

June 17th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Vital Statistics of New South Wales for 1900.

IN spite of the occurrence of the plague the records of the Government statist for New South Wales for the year 1900 show a distinct decrease in mortality and an increase in population. The total deaths numbered 15.118 in 1900, 15,901 in 1899, and 16,661 in 1898. The following table gives some details :—

Deaths from—	1898.	1899.	1900
Measles	609	209	9
Scarlet fever	83	25	9
Influenza	329	360	197
Whooping-cough	241	487	106
Diphtheria	169	60	63
Diarrhœa	625	468	447
Intemperance	122	126	88
Rheumatic fever	74	87	49
Epilepsy	107	133	90
Convulsions	433	443	380
Bronchitis	777	641	609
Pneumonia	973	927	787
Pleurisy	127	116	81
Croup	86	39	25
Suicide	165	185	145
Totals	4820	4316	2985

In some of the diseases more generally connected with childhood the shrinkage was very noticeable indeed, and in those of the respiratory system the falling-off was almost equally striking. There were, however, increases in other directions. The 104 deaths from plague wholly represented an increase and amongst the preventable diseases the 398 deaths from typhoid fever showed an increase of 51. From old age, apoplexy, syncope, diseases of the digestive organs, and heart disease there was also a greater mortality; cancer carried off 765 victims, an increase of four; and phthisis 1077, an increase of eight. The 50 cases of murder and manslaughter showed an increase of 12, while accidents claimed 992, an increase of 110. Privation was the cause of 25 deaths, a decrease of two.

Health of Sydney.

The first quarterly report for the year 1901 on the health of Sydney submitted to the Water and Sewerage Board by its medical officer, Mr. T. Mailler Kendall, stated that the deaths from general causes were less than in the corresponding period of last year. There had been a decrease in the mortality from diarrhœa and typhoid fever and an increase in that from phthisis and diphtheria. The general sanitary condition had improved and the mortality from preventable disease had diminished in areas of the metropolis formerly insanitary, probably from improved legislation.

Hospitals for the Insane in Victoria.

The Master in Lunacy in Victoria has submitted a special report on the treatment of the insane in that State. He points out that Victoria is much behind New South Wales in its hospitals for the insane. Though there are fewer lunatics in New South Wales that State spends more on their housing and maintenance, the asylums are larger and better equipped, and they are built on the most approved modern plans for the classification of patients, and there is a receiving house for doubtful cases which has existed for 30 years. In Victoria the hospitals are very overcrowded and accommodation for another 600 patients is urgently demanded. A receiving house and a separate hospital for paying patients are also wanted. Dr. McOreery, inspector-general of hospitals for the insane, is in entire agreement with the Master in Lunacy and has pointed out the urgent necessity for reforms for years past, but no notice has been taken by the responsible Minister of the day. A new wing, capable of accommodating 100 patients, has just been opened at the Ballarat Asylum, and another ward of like dimensions will be opened in September. These will relieve the metropolitan asylums to some extent. Dr. McOreery also claims that the percentage of cures effected is better than is believed, being as follows:—1899: Victoria 44 44, New South Wales 42 96 England 39 26; 1900: Victoria 40 09, New South Wales 38 88.

Claim against a Dentist.

A patient recently brought an action against a Sydney dentist for £200 damages for injuries received through the alleged negligent and unskilful manner in which he had made, set, and adjusted certain artificial teeth The chief damage alleged was that the irritation of the badly fitting teeth had originated a cancer of the jaw. The judge said that he was of opinion that the work was of a defective character, but he was doubtful whether he ought to allow damages for more than the amount which the plaintiff had paid for the work. On the whole, however, the balance of evidence was in favour of the view that the cancer was the result of the careless work of the defendant and the judge found for the plaintiff for the amount of £50.

May 17th.

Obituary.

FRANCIS WILLIAM WARRINGTON, M.D. ST. AND., M R.C.S. ENG., L.S A., J.P.

DR. F. W. WARRINGTON was a fine example of the old school of family practitioner and his death is a great loss to Congleton, where he had been in practice for nearly 40 years, and also to the surrounding neighbourhood, for he was well known and esteemed over a considerable portion of the county. Dr. Warrington was born in 1839 and was the son of a respected Mayor of Congleton who held office for several years. He was educated at Longnor School in Staffordshire, a well-known academy in those days, and at Plymouth Grove, Manchester. After his pupilage at the North Stafford Infirmary he entered as a student at King's College Hospital, where he afterwards filled the positions of assistant house physician and resident accoucheur. He obtained the L S.A. diploma in 1861 and the M.R.C.S. Eng. and the M D. St. Andrews in 1862, commencing practice in his native town shortly afterwards. His undoubted skill and ability, together with his sound appreciation of human nature, stood him in good stead and enabled him to establish the very large practice which he carried on until his death, always endeavouring to keep abreast of the times. His sympathetic and noble nature gained for him the warmest affection of his patients and he was trusted and held in high esteem by his professional brethren. Dr. Warrington was remarkable for his untiring energy and the physical and mental work accomplished by him at times would have been an impossibility to most people He was strongly attached to his profession, and his medical friends, who are very numerous, will always delight to linger on the remembrance of his graphic and humorous descriptions of incidents in his medical career. Many live to mourn the death, for he was a man of wide sympathies and a generous benefactor, no story of real sorrow or distress ever being unheeded by him.

DAVID CHARLES DAVIDSON, L.R.C.P., L R C.S. EDIN.,

LIEUTENANT-COLONEL, I.M.S.

THE death of this officer in his fiftieth year took place on May 2nd, 1901, after a long and severe illness, the result of overwork and the effects of the climate of India. After qualifying in Edinburgh he held various hospital appointments in England, amongst them being that of surgeon to the Dorset County Hospital and surgeon to the Birkenhead Hospital. In 1887 he entered the Indian Medical Service and proceeded to India in the following year. After a short period of military duty with the 14th Native Infantry and the 3rd Bombay Light Infantry he was appointed to act as civil surgeon of Shikarpur, and had charge of a large jail with over 1000 prisoners. While superintending the construction of a large portion of the Scinde railway he became a victim to Scinde fever and he came to England to recruit his health. On his return to India he was appointed to the civil surgeoncy of Kaira in Guzerat and subsequently acted as health officer to the Bombay municipality. In 1886 he was ordered to Burmah on field service, where he had charge of a base hospital for native troops. In 1888 he went to Satara as civil surgeon and did some good work at the civil hospital there. While there he added, with the sanction of the Government, a new wing to the building. In 1891 and 1892 he acted as superintendent of Mahableshwar.

In 1894 he was appointed senior surgeon and professor of surgery in the Sir Jamsetjee Jejeebhoy Hospital and lecturer in the Grant Medical College. A year later he was appointed civil surgeon of Dharwar. In 1896, after three months' furlough in England, he was recalled to India for service in connexion with plague and famine work. He was appointed surgeon to the Goculdas Tejpal Hospital in Bombay, but his health breaking down he again obtained furlough. He returned to India as superintendent of Mahableshwar. Colonel Davidson did good work there and at other places in connexion with the plague although he was in constantly failing health. In December of last year he became seriously ill and left India on furlough in March, but after reaching England he only survived 20 days. The deceased officer leaves a widow, three sons, and several daughters.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—In June, 1901, the following candidates passed in the subjects indicated:—

Surgery.—C. H. G. Atkyns, Birmingham; H. de T. Barber (Section I.), Geneva and St. Mary's Hospital; F. J. Birks (Sections I. and II.), Sheffield; E. Courtauld (Sections I. and II.), Royal Free Hospital; W. Garstang (Sections I. and II.) and W. Hickey (Section I.), Manchester; H. C. Hocken (Section I.), Cambridge and Westminster Hospital; D. T. Jones, Middlesex Hospital; R. A. Jones (Section II.), St. Mary's Hospital; D. E. Lockwood (Section I.) and F. M. Payne (Section I.), Royal Free Hospital; B. B. Sansom (Section I.), St. Thomas's Hospital; H. H. Sloane (Section I.), St. Bartholomew's Hospital; H. Smith (Section II.), Birmingham; A. W. D. Thomson, St. George's Hospital; and L. G. W. Tyndall, St. Mary's Hospital.

Medicine.—C. H. G. Atkyns, Birmingham; F. J. Birks (Sections I. and II.), Sheffield; E. Courtauld (Sections I. and II.), Royal Free Hospital; E. N. de V. Dawson (Section II.), St. Thomas's Hospital; J. J. Haverson, London Hospital; W. Hickey (Section II.), Manchester; W. J. Hogg (Sections I. and II.), Belfast and Middlesex Hospital; R. A. Jones (Section II.), St. Mary's Hospital; E. O. Libbey, Leeds; D. Morrow (Sections I. and II.), Middlesex Hospital; A. U. Parkhurst, St. Mary's Hospital; H. H. Sloane (Section I.), St. Bartholomew's Hospital; H. Smith (Sections I. and II.), Birmingham; W. A. Sugden, St. Mary's Hospital; and J. Ward (Sections I. and II.), Sheffield.

Forensic Medicine.—C. H. G. Atkyns, Birmingham; F. J. Birks, Sheffield; J. W. Bowd, St. Bartholomew's Hospital; E. Courtauld, Royal Free Hospital; J. J. Haverson, London Hospital; W. J. Hogg, Belfast and Middlesex Hospital; E. O. Libbey, Leeds; D. Morrow, Middlesex Hospital; A. U. Parkhurst, St. Mary's Hospital; and J. Ward, Sheffield.

Midwifery.—J. W. Bowd, St. Bartholomew's Hospital; E. C. Curtis, Aberdeen and Charing-cross Hospital; E. A. Dunn, Royal Free Hospital; A. E. Henton, St. Mary's Hospital; W. Hickey, Manchester; G. M. Seagrove, St. Bartholomew's Hospital; and A. H. Thomas, St. Mary's Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—C. H. G. Atkyns, J. W. Bowd, E. Courtauld, W. Garstang, J. J. Haverson, W. J. Hogg, D. T. Jones, R. A. Jones, A. U. Parkhurst, A. H. Thomas, L. G. W. Tyndall, and J. Ward.

UNIVERSITY OF CAMBRIDGE.—At the examinations for medical and surgical degrees, Easter term, the following candidates were successful in the subjects indicated:—

THIRD EXAMINATION.

Part I.—F. H. M. A. Beckett, B.A., H. Selwyn; L. Bousfield, B.A., Pembroke; A. P. Bowler, B.A., Sidney Sussex; J. Bradford, B.A., Emmanuel; A. S. Bradley, B.A., Caius; H. C. Brown, B.A., Emmanuel; G. V. Bull, B.A., Caius; C. Burroughs, B.A., Emmanuel; F. R. Carroll, B.A., Trinity; E. L. Claxton, B.A., and G. D. Franklin, B.A., King's; J. C. W. Graham, B.A., Trinity; G. S. Graham-Smith, B.A., Pembroke; E. H. Harrisson, B.A., Clare; E. F. G. T. Heap, B.A., Sidney Sussex; J. P. Headley, B.A., and H. T. Hodgkin, B.A., King's; A. C. Hudson, B.A., and H. L. P. Hulbert, M.A., Trinity; W. W. Jeudwine, B.A., H. Selwyn; A. P. Laycock, B.A., St. John's; G. E. Loveday, B.A., Caius; J. M'Bryde, B.A., King's; D. J. Morgan, B.A., St. John's; A. E. Naish, B.A., and S. Nathan, M.A., Trinity; C. de C. Pellier, M.A., Clare; D. [illegible] us; J. W. Rob, B.A., St. John's; A. R. Rool [illegible] Rolfe, B.A., Clare; F. Sanger, B.A., St. [illegible] B.A., Corpus Christi; C. H. Sedgwick, B.A., Sidney Sussex; F. E. Shipway, B.A., Christ's; A. M. Simpson, B.A., King's; J. E. B. Snell, B.A., B. Spearman, B.A., and R. Spearman, B.A., Caius; G. L. Tuck, B.A., Emmanuel; H. Wacher, B.A., St. John's; G. H. L. Whale, B.A., Jesus; J. Wharton, B.A., St. John's; G. R. Wilson, B.A., Trinity; H. M. Wilson, B.A., Trinity Hall; and F. E. Wood, B.A., Downing.

Part II.—A. P. M. Anderson, B.A., Trinity; A. H. Brehaut, B.A., H. Selwyn; A. R. M. Brenan, B.A., Trinity; J. M. Brydone, Jesus; A. E. Carver, B.A., Clare; F. J. Child, M.A., Christ's; J. S. Clarke, M.A., Caius; L. S. Gaskell, M.A., Christ's; C. H. Glenn, B.A., Pembroke; J. A. Glover, B.A., St. John's; H. Gordon-Smith, B.A., Trinity; A. W. Greig, B.A., Jesus; M. C. Hayward, M.A., Caius; A. E. Hodder, B.A., King's; A. C. Ingram, B.A., St. John's; A. S. Mellor, B.A., King's; C. H. Miller, B.A., Trinity; F. E. Murray, B.A., St. John's; G. H. Orton, B.A., J. C. S. Rashleigh, M.A., and L. Reynolds, B.A., Trinity; H. H. Riddle, B.A., Peterhouse; R. D. Smedley, B.A., Pembroke; A. E. Taylor, B.A., Downing; N. F. Ticehurst, M.A., Clare; J. L. Timmins, B.A., Emmanuel; W. E. Tucker, Caius; F. K. Weaver, B.A., Trinity; and R. F. Williams, B.A., Caius.

During the academical year just closed 20 candidates were admitted to the M.D. degree, one to the M.C., 50 to the M.B., and 61 to the B.C.

UNIVERSITY OF BRUSSELS: JUNE EXAMINATION.—The following practitioners passed and obtained the M.D. degree:—

L. Harris-Liston, Exeter; G. H. Lancashire, Didsbury; H. C. Procter (Honours), Ladysmith, Natal; E. F. Lamport (Honours), London; E. Haslam (Honours), London; and T. B. Haig, London.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin*: Dr. Arthur Nicolaier of Göttingen has been recognised as *privat-docent* of Internal Medicine and Dr. Johann Friedenthal as *privat-docent* of Physiology.—*Bordeaux*: Dr. Bégouin has been appointed *professeur agrégé* of Surgery and Dr. Andérodias *professeur agrégé* of Midwifery.—*Breslau*: Dr. H. Sachs, *privat-docent* of Neurology, has been promoted to an Extraordinary Professorship.—*Erlangen*: Dr. Graser, Professor of Surgery in Rostock, has been offered the chair vacated by the death of Dr. von Heineke.—*Groningen*: Dr. Huizinger, Professor of Physiology, is retiring. Dr. Hamburger of Utrecht has been appointed to succeed him.—*Halle*: Dr. Gebhardt has been recognised as *privat-docent* of Anatomy.—*Iurieff* (*Dorpat*): Dr. A. N. Solovieff of Moscow has been appointed to the chair of Midwifery. Dr. Gubareff of Moscow has been appointed Extraordinary Professor of Midwifery and Children's Diseases.—*Leyden*: Dr. van Walsen has been appointed Professor of Pathological Anatomy.—*Lille*: Dr. Lambert has been appointed *professeur agrégé* of Surgery.—*Lyons*: Dr. Villard and Dr. Tixier have been appointed *professeurs agrégés* of Surgery, and Dr. Fabre *professeur agrégé* of Midwifery.—*Montpellier*: Dr. Jeanbrau has been appointed *professeur agrégé* of Surgery.—*Moscow*: Dr. Gulevich of Kharkoff has been appointed Extraordinary Professor of Medical Chemistry. Dr. Karusin has been appointed Professor of Descriptive Anatomy.—*Nancy*: Dr. Michel has been appointed *professeur agrégé* of Surgery.—*Paris*: Dr. Photinos Panas has been obliged to give up his chair of Ophthalmology on account of the state of his health. Dr. Lapersonne of Lille has been appointed to succeed him. Dr. Marion, Dr. Gosset, and Dr. Auvray have been appointed *professeurs agrégés* of Surgery, and Dr. Demelin and Dr. Potocki *professeurs agrégés* of Midwifery.—*Prague* (*Bohemian University*): Dr. Heinrich Chalupecky has been recognised as *privat-docent* of Ophthalmology.

A CENTENARIAN.—It is stated that Mrs. Priest, who died at Bath on June 20th, had attained the age of 104 years and 10 months. The deceased had had 10 children, of whom three sons served in the Crimean war, and there are living 34 grand-children and nearly a dozen great-grandchildren.

QUALIFICATIONS OF SANITARY INSPECTORS.—At a recent meeting of the St. Germans (Cornwall) District Council a candidate was selected for the post of sanitary inspector who did not possess any certificate of sanitary knowledge. At the meeting of the council held on June 20th it was, however, resolved that the question of the appointment should be reconsidered and a certificated sanitary inspector appointed.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—It is stated that Dr. Isambard Owen has been asked to succeed the late Professor J. Viriamu Jones as principal of the University College of South Wales and Monmouthshire.

IN MEMORIAM, QUEEN VICTORIA.—Towards the fund to be raised for completing the Preston and County of Lancaster Royal Infirmary as a memorial to the late Queen Mr. Richard Calvert, cotton-spinner, of Preston, has promised £5000.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A numerous gathering of the members of the above society and their friends assembled to hear the Cavendish Lecture on "Acute Cardiac Failure," which was delivered by Sir Richard Douglas Powell at the Town Hall, Hammersmith, on June 21st. The lecture, which is published at p 1811 of our present issue, was followed by a conversazione in the large hall where were exhibited various medical and surgical novelties by well-known firms.

CHARING CROSS HOSPITAL.—Professor Clifford Allbutt, in his address to the students of the Charing Cross Hospital Medical School on the occasion of the presentation of prizes on June 26th, referred in the course of his remarks to the disastrous effect of extinguishing the natural curiosity born with every man to inquire into the nature of things. He also improved the opportunity by administering a crushing answer to those who have sought to discredit the hospitals by saying that patients were experimented upon by the physicians in attendance. An apt quotation from Hobbes and a singularly lucid explanation of the scientific methods of teaching medicine at the present time concluded a most interesting and earnest address which was greatly appreciated by the numerous company assembled at the Charing Cross Hospital Medical School.

CONVERSAZIONE OF THE WORSHIPFUL SOCIETY OF APOTHECARIES OF LONDON.—A conversazione was held in the Apothecaries' Hall, Water-lane, on June 26th when a very distinguished company was present to witness the many scientific exhibits displayed and to listen to the excellent programme of music that was provided. The visitors were received by the Master, Mr. Charles Browne, with whom were the wardens, Mr. T. E. Burton Brown and Mr. William Parson, and the clerk, Mr. James Richard Upton. In the Wheeler room a very excellent series of natural colour photographs were shown upon the screen by Mr E. Sanger-Shepherd, who is the author of the process, while in the large hall there was a demonstration of wireless telegraphy, and in other rooms various electrical phenomena were illustrated and the electrophone was in working order so that the visitors could hear the various entertainments going on in London.

PAST AND PRESENT WEST LONDON HOSPITAL DINNER —The great success that has attended the work of the post-graduate school attached to the West London Hospital was the occasion of much congratulation and rejoicing at the Past and Present West London Hospital dinner held at the Empire Rooms, Trocadéro, Piccadilly-circus, London, W., on June 25th. The chairman, Mr. F. Swinford Edwards, was well supported in numbers, and speaking to the toast of "The West London Hospital" pointed out how well suited the hospital was to supply the wants and necessities of the post-graduate school Since 1896 over 270 men had gone through the school and the financial position resulting from the school's success was so satisfactory that new buildings were in progress. It was very pleasant to hear the reply to this toast from Mr. A. Hubbard, J.P., one of the executive committee of the hospital, and it was quite evident that there was no want of harmony between the medical staff and the hospital management. Mr. L. A. Bidwell proposed "The Post-Graduates" and ascribed the popularity of the school to the fact that the medical men attending were not shown a collection of rare cases but saw every-day practice. The members of the West London post-graduate course enjoyed the advantages of studying in the wards of a hospital and also assisted at operations.

Parliamentary Intelligence.

HOUSE OF COMMONS.

THURSDAY, JUNE 20TH.

The Examination of Invalided Soldiers

Sir ELLIOTT LEES asked the Secretary of State for War whether he was aware that officers and men invalided home by medical boards at [illegible] and the taxpayers, orders could be given that all patients about to undergo operations in England should be sent home with as little delay as possible, and whether in all cases the number of medical boards before which invalided officers and men had to pass prior to being sent home could be reduced —Mr BRODRICK replied I am not aware that persons invalided home are examined by more than one board except in cases where the patient on his way to the coast develops further illness and has to undergo examination with a view to the extension of his sick leave The information at my disposal tends to show that patients are not detained unnecessarily at Wynberg I will, however, draw the attention of the Commander-in Chief in South Africa to the points raised by the question with a view to his taking such action as may be deemed necessary.

The Army Medical Department.

Captain NORTON asked the Secretary of State for War whether, in view of the fact that there was at the head of the Army Medical Department at the present time only an Acting Director General shortly about to retire from the service, he would say when a new Director-General would be appointed —Mr. BRODRICK replied No; I can make no statement on this subject. Various measures for the reorganisation of the Medical Department are in progress.

Medical Officers of Health in Scotland

[illegible] but as the medical men did not possess the statutory qualifications the appointments were not in terms of the Public Health Acts and were not recognised by the Local Government Board.

FRIDAY, JUNE 21ST

Fish Culture.

Mr GERALD BALFOUR President of the Board of Trade, announced that he proposes to appoint a departmental committee "to inquire and [illegible]"

TUESDAY, JUNE 25TH

Admission of Disease from Abroad.

Sir HOWARD VINCENT asked the President of the Local Government Board (1) if his attention had been called to the fact that all aliens suffering from dangerous contagious diseases were excluded from admission to the United States under the Immigration Laws of Con- [illegible] regards cholera cases the regulations required the isolation in hospital [illegible] regulations [illegible]

Typhoid Fever among the Troops

Lord STANLEY, in reply to Sir WALTER FOSTER, said that for the four weeks ended April 26th the approximate number of admissions among the troops in South Africa for typhoid fever was 1484 and the number of deaths 187

WEDNESDAY, JUNE 26TH.

[illegible]

Beer Bill.

This Bill also was referred to the Standing Committee on Law. It divides beer into two classes—"malt beer" which is defined as beer brewed from barley malt with the addition only of hops, yeast, and water, and "part malt beer," defined as any beer other than "malt beer"—and it provides for the two classes being labeled so that the public may distinguish between them The Bill is strongly opposed and is not likely to be passed during the present session.

ROYAL COMMISSION ON ARSENICAL POISONING.

THURSDAY, JUNE 20TH.

THE Commission held a meeting for the examination of witnesses in the Westminster Palace Hotel, London. Lord KELVIN occupied the chair, and the other members of the Commission present were Sir William Church, Sir W. Hart-Dyke, M P., Professor Thorpe, Dr. B A. Whitelegge, and Mr. Cosmo Bonsor, with Dr. G. S Buchanan, of the Local Government Board, secretary.

Mr. CLARE SEWELL READ, ex-member of Parliament and ex-secretary of the Local Government Board, said that he had been appointed along with Mr. Henry Stopes to give evidence on behalf of the Central Chamber of Agriculture. He had been engaged in farming for 60 years, but he had no practical acquaintance with either malting or brewing He did not consider that sugar in beer was necessarily injurious to health, but in his opinion some of the glucoses used were injurious. He was a member of the Beer Materials Committee, and his view was that if the minority report of that body had been adopted it was quite possible that the recent beer-poisoning epidemic might have been averted. For one thing there would have been proper supervision of the materials from which beer was made. As for the present action of the Somerset House authorities, while it was a very good safeguard for the revenue, it was a very poor safeguard for the public health. He endorsed the recommendation of the Select Committee of the House of Commons for the appointment of a court of reference. Such a court should be composed of competent experts and sound business men, and its duty would be to fix standards of purity and decide other points arising out of the Sale of Food and Drugs Acts. It was perfectly ridiculous to ask a farmer for a guarantee that his barley was free from arsenic, and if he were a maltster he should simply guarantee that he had used good fuel, and if a hop-grower that he had exercised all due care in the growth and curing of his hops. Some of the gentlemen who gave evidence at the inquiry of the Manchester Central Brewers' Association also gave evidence before the Beer Materials Committee. When they gave the latter evidence they said—and they convinced the majority of the committee—that there were no ingredients which were harmful to health used in brewing, whereas in this later investigation they seemed to believe that almost every ingredient used in brewing was more or less poisonous It seemed to him just this—that they could prove anything when they liked and nothing when they desired to do so. The effect upon farmers of these scientific scares, which mostly proved to be wrong, was that when there was a really good and sound scientific discovery they were very slow to believe it and that was bad for farmers and the country generally. He was chairman of the Adulteration Committee upon whose report the Sale of Food and Drugs Act, 1875, was founded. The committee wished to bring beer into that Act but they found that they could not do so because there was no legal definition of beer. Asked whether he would propose a definition of beer witness said that he advocated the passing of the Beer Bill now before the House of Commons. It was true that the Bill was not a pure-beer Bill, but it had a declaration and a definition of what beer should be and he thought that it would have been disrespectful to this Royal Commission if the promoters of the Bill had attempted to legislate on the question of arsenic in beer. In connexion with the drawing up of the report of the Adulteration Committee on which the Sale of Food and Drugs Act was founded they felt it very difficult to define adulteration. They decided that an article of the nature, substance, and quality demanded by the customer should be given and he believed that, generally speaking, this had proved a successful definition. He had had a considerable experience in investigating sewage farming, for he was appointed to a departmental committee which inquired into all the systems of sewage farming pursued in Great Britain and on the continent. The most filthy substances were used for the purposes of irrigation, not in but over the soil and very frequently over the different vegetables and the grass, and he never heard of any disorder or poisoning happen from stock eating the vegetables or the grass or from the milk of the stock. He hoped that this Commission would report in favour of some such measure as the Beer Bill He should like to see more diligent supervision exercised over the ingredients used in beer by the medical officers of health or other officers of the local authorities and in addition the establishment of a standard of purity. In his opinion arsenic in malt came from bad fuel and consequently he thought that gas coke should be prohibited. He was not opposed to the use of glucose or invert sugar by brewers, but he thought that the fact of the use of either of these things should be made known.

Mr. HENRY STOPES, maltster's architect and engineer, in the course of examination said that he had invented and designed two-floor malt kilns and had designed and supervised the erection of the largest pneumatic malt house in Britain. In experience it was found that they could not get malt suitable for brewing in this country without bringing the products of combustion into direct contact with the grain. It was necessary to have these products as well as hot air. Kilns had been tried on the German principle, but they had been a failure in this country. He did not think that sufficient evidence had been produced of the presence of arsenic in barley or hops. Superphosphates and other manures added to land would supply a negligible amount, but it had not yet been proved, although experiments had been conducted with a view to testing it, that plants or seeds picked up arsenic in any form. In the various uses of potatoes in Germany, if the tubers picked up arsenic it would certainly have been found No harm had ever been observed in the experiments at Rothampsted with 3¼ cwts. of superphosphates per acre. The loose charges made against manures in this connexion were injurious to the farmers. It was the same also with regard to fuel. The amount of arsenic in coal, coke, charcoal, or other fuel was exceedingly small; in many oven cokes there was absolutely none. He had always advised maltsters to stop the use of gas coke; but that was because of the fumes being disagreeable to the workers. As for charcoal, it was more expensive than the dearest anthracite coal, and he thought that hop-growers who had adopted it should be encouraged to continue its use. The sulphur used by maltsters or hop-growers was not sufficient to carry more than a negligible amount of arsenic through to the beer. He desired to confirm the evidence of other witnesses that arsenic was never found in barley. The use of substitutes for hops was small and now that entry of use by brewers would shortly have to be made it was probable that no risk of poisoning would arise from this source. The use of substitutes for malt was rapidly increasing. It already amounted to 2,000,000 quarters per annum. The extreme cheapness of glucose, sugar, and some of the other adjuncts had led to depreciation in the price of barley and excessive competition had led to the use of inferior fuels by maltsters. As these substitutes did not possess the vital characteristics of barley malt, which constituted the essential element of beer, recourse had necessarily been made to large quantities of powerful antiseptics as preservatives in beer. Witness supported Mr. Read in his advocacy of the establishment of a court of reference and the fixing of standards of purity.

On the conclusion of Mr. Stopes's examination the Commission adjourned.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

ANDERSON, JOSEPH, M.B., C.M. Aberd., has been appointed Honorary Surgeon to the Preston and County of Lancaster Royal Infirmary, vice J. A. Rigby, M D Lond., appointed Consulting Surgeon.

ANDREWS, HENRY RUSSELL, M D., B.S. Lond., L.R.C.P. Lond., has been re-appointed Obstetrical Registrar and Obstetrical Tutor to the London Hospital.

AUSTEN, HAROLD, M.D., B S. Lond., M.R.C.S., L.D.S. Eng., has been appointed Assistant Dental Surgeon to the Dental Hospital of London.

BABST, C. T. U., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer of Health of Willington Quay, Northumberland.

BENSLEY, V. C., M.R.C.S. Eng, L.R.C.P. Lond., has been appointed Third Resident Surgeon at the Somerset Hospital, South Africa.

CADDY, ADRIAN, M.B Lond., L.R C.P. Lond., M.R.C.S. Eng, has been appointed Resident Medical Officer to the Parish Infirmary, Brownlow-hill, Liverpool.

CAMPBELL, P. E, M.B, C.M. Edin., has been appointed Medical Superintendent of Caterham Asylum, Surrey.

CLARK, SYDNEY, M.R C S, Eng, L.R.C.P. Lond., has been appointed Honorary Visiting Medical Officer to the Victoria Home for Invalid Ladies, vice Dr. Chadwick, appointed Consulting Physician.

CRINION, L. A. J., M B., B Ch. R.U.I., has been appointed Medical Officer of Blessington No. 1 Dispensary District in the Naas Union.

DON, JAMES, M.B. Aberd, has been appointed Public Vaccinator of Newcastle-upon-Tyne

EAMES, E S. B., L.R.C P. Lond., M.R.C.S. Eng., has been appointed District Medical Officer to the Honiton Union.

EURICH, F. W., M.D., C.M. Edin., has been appointed Pathologist and Bacteriologist to the Corporation of Bradford.

FARRANT, CHARLES, L.R.C.P. Lond., M.R.C.S. Eng., has been appointed Medical Officer for the St. James's District by the Taunton Board of Guardians, vice Samuel Farrant, resigned.

GRUGGEN, WILLIAM, L R.C P. Irel., L.F.P.S. Glasg., D.P.H. Camb., has been appointed Medical Officer of Health of Tring.

HARRIS, J. H., M.R.C.S. Eng., L S A., D.P.H. Cantab, has been re-appointed Medical Officer of Health for the Borough of Dartmouth.

HILL, CHARLES A., M B., B.A. Cantab, D.P.H. Vict, has been appointed Senior Assistant Physician to the Liverpool Hospital for Consumption and Chest Diseases.

HOOD, N. L., M D., D C. Cantab, has been appointed Honorary Surgeon to the York County Hospital.

HUNT, J. W., M.B., has been appointed Second Resident Surgeon at the Somerset Hospital, South Africa.

LE FANU, G. E. H., M B Aberd, has been appointed Assistant Medical Officer to the Derby Borough Asylum.

MAY, JOSEPH, M.R.C.S. Eng., L.S A., has been re-appointed Medical Officer of Health of the Borough of Devonport.

MOORE, S. G., M.B, Ch.B. Vict., D.P.H. Eng. Conj, has been appointed Medical Officer of Health of Huddersfield.

RAY, J. H., M B, Ch.M. Vict., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Manchester Children's Hospital.

N B.—A fee of 5s. is charged for the insertion of Notices of Births Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

"MEDICAL TESTIMONIALS TO QUACKERY."

To the Editors of THE LANCET.

SIRS,—The explanation which Dr. Burrow and myself offer in regard to your comments in THE LANCET of June 22nd, p. 1808, headed "Medical Testimony to Quackery," is as follows. The man in question called on us personally at our own houses introducing himself as a corn-cutter. He produced a book containing some hundreds of testimonials from medical men in regard to corn-cutting; we added our names. We had no suspicion that the man was anything more than what he professed to be, or that the testimonials were to be used as advertisements, either in the local papers or in any other unbecoming manner. No one was more surprised than we were to see our names in the advertisement column of the *Lancaster Observer* of June 7th, palpably recommending a man who treated "varicose veins, fungous tumours, ingrowing nails, &c." The same day we consulted a solicitor who, on the 12th inst., had in his possession a written guarantee from Mr. S. that future publication would cease. They certainly have not reappeared in this district. We were thus the unconscious victims of a quack, but we have done all in our power since to prevent our names being connected in any way with him. On behalf of Dr. Burrow and myself,

I am, Sirs, yours faithfully,

W. DODGSON BARROW.

Dalton-square, Lancaster, June 26th, 1901.

To the Editors of THE LANCET.

SIRS,—You will find below the names of two of the four medical men whom you attacked in the last issue of your paper under the above heading and whose names you so mercifully withheld. You say that we must be trusting and unsophisticated and that we are guilty of conduct requiring explanation. Altogether you seem to have bottled up a considerable store of virtuous indignation. You publish this attack in your widely-read journal without having in any way made yourself acquainted with the facts of the case; you trusted entirely to the evil disposed person whom you refer to as your "sour correspondent." We ask you to publish our reply to that attack, not on account of any rule of medical etiquette, but as a matter of justice and fair-play. The medical men of this district understand exactly the conditions under which these testimonials were given and the good feeling that exists amongst the members of the profession here is not likely to be disturbed by the efforts of your "sour correspondent." We are but poor general practitioners but we yield to no one in the desire to uphold the honour of our profession. We do not think its status is likely to be raised by medical men making themselves ridiculous by slavishly adhering to some supposed rules of medical etiquette which, if they exist, are manifestly absurd and silly. If a man cuts our corns, nails, or hair, and he does it well, or if a man supplies us with good bicycles or motor-cars, we see no objection to testifying to it, even though we do belong to the medical profession. The advertisement in the *Lancaster Observer* was highly objectionable and how it was that our names appeared in it admits of a very simple explanation. We are not going to give you that explanation and we are perfectly indifferent to any opinion that you may now form on the subject.

We are, Sirs, yours truly,

PATRICK F. MANNIX,
BERTRAM W. HOGARTH.

Lancaster, June 22nd, 1901.

*** "A sour correspondent" should have read, had it been properly printed, "*as our correspondent*."—ED. L.

"THE HAGEY TREATMENT FOR INEBRIETY."

To the Editors of THE LANCET.

SIRS,—Could any of your readers give me information as to the utility of the "Hagey treatment for inebriety, &c."? A patient of mine of moderate means is urged by his relatives to try "the cure," the fee for which is 25 guineas, payable beforehand. I should not like to see him fleeced of his money.

I am, Sirs, yours faithfully,

M.D.

June 24th, 1901.

CATERPILLAR RASH.

To the Editors of THE LANCET.

SIRS,—A few days ago two children were playing with the hairy caterpillar of which I inclose two specimens. They both awoke next day with a rash composed of little vascular papules, accompanied with considerable irritation. While playing with the caterpillars the elder child had worn gloves and in her case the rash was confined to the face and neck, for, as it was a windy day, she kept brushing her long hair back from her eyes, and she complained almost immediately of smarting in the eyelids; the younger child, being ungloved, had his hands covered with the rash, besides a patch on his neck and cheek where he might have rubbed them. They had both being playing with other kinds of caterpillars for several weeks without any ill effects. Though this is the third day, the rash has scarcely begun to subside, and the practitioner who attended them says that the rash has some resemblance to the early stage of small-pox. T caterpillar was swarming on the may-trees during the first wee June, and as it is clear that the poison was conveyed merely by to and the insects are very tempting to children it seems worth whil call public attention to the matter.

I am, Sirs, yours faithfully,

G. I. THOMSO

Northampton, June 26th.

*** The larvæ inclosed by our correspondent are those of the g tail or yellow-tail moth. The popular name of the caterpillar, in south of England at least, is "palmer worm." The urtica property of these larvæ, or rather of the hairs with which the adorned, is well known to entomologists, although we c call to mind any medical book in which the rash is mentio The scientific name of the moth is Liparis Auriflua. The urtica property is probably purely mechanical, for the chrysalis and cocoon which also contain the hairs give rise to the same effect, will also the moth when just out of the chrysalis. The process caterpillar of Southern Europe acts in the same way, as also doe large hairy spider, the mygale, found in South America and West Indies.—ED. L.

THE ATTENDANCE OF VOLUNTEER MEDICAL OFFICERS CAMP.

To the Editors of THE LANCET.

SIRS,—In answer to the query of "A Volunteer Medical Officer" THE LANCET of June 15th, p. 1738, perhaps you will kindly publish the following information. Before going to camp the commanding of a regiment should send to the senior medical officer asking to detail medical officers for duty in camp. The senior me officer then allocates the days for duty to the various me officers under his orders, having regard, as far as possible, to wishes and requirements of those who are senior in rank in the place and then to the juniors or more recently appointed men. senior medical officer of the battalion is practically responsible the health of the regiment in camp.

I am, Sirs, yours faithfully,

SURGEON-LIEUTENANT-COLONEL.

June 17th, 1901.

THE DESCENT OF MAN.

WAR is sometimes said to be brutalising, but the following delig story, which our contemporary the *Westminster Gazette* publicity to in its issue of June 24th, shows a degradation in stro which may well "stagger humanity":—

> "It is stated that a young officer at the front recently home to his father: 'Dear Father,—Kindly send me £50 at lost another leg in a stiff engagement, and am in hospital with means.' The answer was: 'My dear Son,—As this is the fo leg you have lost, according to your letters, you ought to be ac tomed to it by this time. Try and wobble along on any others y may have left.'"

◆

K.—We think our correspondent may give the solicitors any infor tion which he would be bound to give on oath if subpœnaed, b will be well to give this information verbally and not in writing

Robin.—Our correspondent will get the information which he req if he will write to the Secretary, Royal College of Surg Edinburgh.

Medical Diary for the ensuing We

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only; AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. I. of 1901, which is completed with the issue of to-day, will be given in the next number of THE LANCET.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1901 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them! Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, MR. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

Terms for Position Pages and Serial Insertions on application.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. tisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.
